Title Exploratory Graph Analysis – a Framework for Estimating the Number of Dimensions in Multivariate Data using Network Psychometrics

Version 2.3.0

Date 2025-04-09

Maintainer Hudson Golino <hfg9s@virginia.edu>

Description Implements the Exploratory Graph Analysis (EGA) framework for dimensionality and psychometric assessment. EGA estimates the number of dimensions in psychological data using network estimation methods and community detection algorithms. A bootstrap method is provided to assess the stability of dimensions and items. Fit is evaluated using the Entropy Fit family of indices. Unique Variable Analysis evaluates the extent to which items are locally dependent (or redundant). Network loadings provide similar information to factor loadings and can be used to compute network scores. A bootstrap and permutation approach are available to assess configural and metric invariance. Hierarchical structures can be detected using Hierarchical EGA. Time series and intensive longitudinal data can be analyzed using Dynamic EGA, supporting individual, group, and population level assessments.

Description

Implements the Exploratory Graph Analysis (EGA) framework for dimensionality and psychometric assessment. EGA estimates the number of dimensions in psychological data using network estimation methods and community detection algorithms. A bootstrap method is provided to assess the stability of dimensions and items. Fit is evaluated using the Entropy Fit family of indices. Unique Variable Analysis evaluates the extent to which items are locally dependent (or redundant).

Network loadings provide similar information to factor loadings and can be used to compute network scores. A bootstrap and permutation approach are available to assess configural and metric invariance. Hierarchical structures can be detected using Hierarchical EGA. Time series and intensive longitudinal data can be analyzed using Dynamic EGA, supporting individual, group, and population level assessments.

auto.correlate Automatic correlations

Description

This wrapper is similar to cor_auto. There are some minor adjustments that make this function simpler and to function within EGAnet. NA values are not treated as categories (this behavior differs from cor_auto)

Usage

```
auto.correlate(
   data,
   corr = c("cosine", "kendall", "pearson", "spearman"),
   ordinal.categories = 7,
   forcePD = TRUE,
   na.data = c("pairwise", "listwise"),
   empty.method = c("none", "zero", "all"),
   empty.value = c("none", "point_five", "one_over"),
   verbose = FALSE,
   ...
)
```

Arguments

data	Matrix or data frame. Should consist only of variables to be used in the analysis
corr	Character (length = 1). The standard correlation method to be used. Defaults to "pearson". Using "pearson" will compute polychoric, tetrachoric, polyserial, and biserial correlations for categorical and categorical/continuous correlations by default. To obtain "pearson" correlations regardless, use cor. Other options of "kendall" and "spearman" are provided for completeness and use cor. cosine is also available
	Numeric (length = 1). Up to the number of categories before a variable is considered continuous. Defaults to 7 categories before 8 is considered continuous
forcePD	Boolean (length = 1). Whether positive definite matrix should be enforced. De- faults to TRUE
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
	 "pairwise" — Computes correlation for all available cases between two variables "listwise" — Computes correlation for all complete cases in the dataset
empty.method	Character (length = 1). Method for empty cell correction in polychoric.matrix. Defaults to "none" Available options:
	 "none" — Adds no value (empty.value = "none") to the empirical joint frequency table between two variables
	• "zero" — Adds empty.value to the cells with zero in the joint frequency table between two variables
	• "all" — Adds empty. value to all in the joint frequency table between two variables
empty.value	Character (length = 1). Value to add to the joint frequency table cells in polychoric.matrix. Defaults to "none". Accepts numeric values between 0 and 1 or specific methods:
	 "none" — Adds no value (0) to the empirical joint frequency table between two variables

	 "point_five" — Adds 0.5 to the cells defined by empty.method
	 "one_over" — Adds 1 / n where n equals the number of cells based on empty.method. For empty.method = "zero", n equals the number of zero cells
verbose	Boolean (length = 1). Whether messages should be printed. Defaults to FALSE
	Not actually used but makes it easier for general functionality in the package

Author(s)

Alexander P. Christensen <alexpaulchristensen@gmail.com>

Examples

```
# Load data
wmt <- wmt2[,7:24]
# Obtain correlations
wmt_corr <- auto.correlate(wmt)</pre>
```

boot.ergoInfo Bootstrap Test for the Ergodicity Information Index

Description

Tests the Ergodicity Information Index obtained in the empirical sample with a distribution of EII obtained by a variant of bootstrap sampling (see **Details** for the procedure)

Usage

```
boot.ergoInfo(
  dynEGA.object,
  EII,
  use = c("edge.list", "unweighted", "weighted"),
  shuffles = 5000,
  iter = 100,
  ncores,
  verbose = TRUE
)
```

Arguments

dynEGA.object	A dynEGA or a dynEGA.ind.pop object. If a dynEGA object, then level = c("individual", "population") is required
EII	A ergoInfo object used to estimate the Empirical Ergodicity Information Index or the estimated value of EII estimated using the ergoInfo function. Inherits
	use from ergoInfo. If no ergoInfo object is provided, then it is estimated

use	Character (length = 1). A string indicating what network element will be used to compute the algorithm complexity, the list of edges or the weights of the network. Defaults to use = "unweighted". Current options are:
	 "edge.list" — Calculates the algorithm complexity using the list of edges "unweighted" — Calculates the algorithm complexity using the binary weights of the encoded prime transformed network. 0 = edge absent and 1 = edge present
	 "weighted" — Calculates the algorithm complexity using the weights of encoded prime-weight transformed network
shuffles	Numeric. Number of shuffles used to compute the Kolmogorov complexity. Defaults to 5000
iter	Numeric (length = 1). Number of replica samples to generate from the bootstrap analysis. Defaults to 100 (1000 for robustness)
ncores	Numeric (length = 1). Number of cores to use in computing results. Defaults to ceiling(parallel::detectCores() / 2) or half of your computer's process- ing power. Set to 1 to not use parallel computing
	If you're unsure how many cores your computer has, then type: parallel::detectCores()
verbose	Boolean (length = 1). Should progress be displayed? Defaults to TRUE. Set to FALSE to not display progress

Details

In traditional bootstrap sampling, individual participants are resampled with replacement from the empirical sample. This process is time consuming when carried out across v number of variables, n number of participants, t number of time points, and i number of iterations. Instead, boot.ergoInfo uses the premise of an ergodic process to establish more efficient test that works directly on the sample's networks.

With an ergodic process, the expectation is that all individuals will have a systematic relationship with the population. Destroying this relationship should result in a significant loss of information. Following this conjecture, boot.ergoInfo shuffles a random subset of edges that exist in the **population** that is *equal* to the number of shared edges it has with an individual. An individual's unique edges remain the same, controlling for their unique information. The result is a replicate individual that contains the same total number of edges as the actual individual but its shared information with the population has been scrambled.

This process is repeated over each individual to create a replicate sample and is repeated for X iterations (e.g., 100). This approach creates a sampling distribution that represents the expected information between the population and individuals when a random process generates the shared information between them. If the shared information between the population and individuals in the empirical sample is sufficiently meaningful, then this process should result in significant information loss.

How to interpret the results: the result of boot.ergoInfo is a sampling distribution of EII values that would be expected if the process was random (null distribution). If the empirical EII value is *greater than* or not significantly different from the null distribution, then the empirical data can be expected to be generated from an nonergodic process and the population structure is not sufficient to describe all individuals. If the empirical EII value is significantly *lower than* the null distribution, then the empirical data can be described by the population structure – the population structure is sufficient to describe all individuals.

boot.ergoInfo

Value

Returns a list containing:

empirical.ergoInfo	
	Empirical Ergodicity Information Index
boot.ergoInfo	The values of the Ergodicity Information Index obtained in the bootstrap
p.value	The two-sided <i>p</i> -value of the bootstrap test for the Ergodicity Information Index. The null hypothesis is that the empirical Ergodicity Information index is equal to or greater than the expected value of the EII with small variation in the population structure
effect	Indicates wheter the empirical EII is greater or less then the bootstrap distribution of EII.
interpretation	How you can interpret the result of the test in plain English

plot(testing.ergoinfo2)
## End(Not run)
```

boot.wmt

bootEGA Results of wmt2Data

Description

bootEGA results from boot.wmt <- bootEGA(wmt2[,7:24], seed = 1234)</pre>

Usage

```
data(boot.wmt)
```

Format

A list with 12 objects (see Value in bootEGA)

Examples

data("boot.wmt")

bootEGA

Description

bootEGA Estimates the number of dimensions of iter bootstraps using the empirical zero-order correlation matrix ("parametric") or "resampling" from the empirical dataset (non-parametric). bootEGA estimates a typical median network structure, which is formed by the median or mean pairwise (partial) correlations over the *iter* bootstraps (see **Details** for information about the typical median network structure).

Usage

```
bootEGA(
  data,
  n = NULL,
  corr = c("auto", "cor_auto", "cosine", "pearson", "spearman"),
  na.data = c("pairwise", "listwise"),
 model = c("BGGM", "glasso", "TMFG"),
  algorithm = c("leiden", "louvain", "walktrap"),
  uni.method = c("expand", "LE", "louvain"),
  iter = 500,
  type = c("parametric", "resampling"),
  ncores,
  EGA.type = c("EGA", "EGA.fit", "hierEGA", "riEGA"),
  plot.itemStability = TRUE,
  typicalStructure = FALSE,
  plot.typicalStructure = FALSE,
  seed = NULL,
  verbose = TRUE,
  . . .
)
```

Arguments

data	Matrix or data frame. Should consist only of variables to be used in the analysis
n	Numeric (length = 1). Sample size if data provided is a correlation matrix
corr	Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:
	 "auto" — Automatically computes appropriate correlations for the data using Pearson's for continuous, polychoric for ordinal, tetrachoric for binary, and polyserial/biserial for ordinal/binary with continuous. To change the number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details) "cor_auto" — Uses cor_auto to compute correlations. Arguments can be

passed along to the function

	 "cosine" — Uses cosine to compute cosine similarity "pearson" — Pearson's correlation is computed for all variables regardless of categories "spearman" — Spearman's rank-order correlation is computed for all variables regardless of categories
	For other similarity measures, compute them first and input them into data with the sample size (n)
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
	 "pairwise" — Computes correlation for all available cases between two variables
	• "listwise" — Computes correlation for all complete cases in the dataset
model	Character (length = 1). Defaults to "glasso". Available options:
	 "BGGM" — Computes the Bayesian Gaussian Graphical Model. Set argument ordinal.categories to determine levels allowed for a variable to be considered ordinal. See ?BGGM::estimate for more details "glasso" — Computes the GLASSO with EBIC model selection. See EBICglasso.qgraph for more details "TMEG" — Computes the TMEG method. See TMEG for more details
algorithm	Character or igraph cluster_* function (length = 1). Defaults to "walktrap". Three options are listed below but all are available (see community.detection for other options):
	 "leiden" — See cluster_leiden for more details "louvain" — By default, "louvain" will implement the Louvain algorithm using the consensus clustering method (see community.consensus for more information). This function will implement consensus.method = "most_common" and consensus.iter = 1000 unless specified otherwise "walktrap" — See cluster_walktrap for more details
uni.method	Character (length = 1). What unidimensionality method should be used? De- faults to "louvain". Available options:
	• "expand" — Expands the correlation matrix with four variables correlated 0.50. If number of dimension returns 2 or less in check, then the data are unidimensional; otherwise, regular EGA with no matrix expansion is used. This method was used in the Golino et al.'s (2020) <i>Psychological Methods</i> simulation
	• "LE" — Applies the Leading Eigenvector algorithm (cluster_leading_eigen) on the empirical correlation matrix. If the number of dimensions is 1, then the Leading Eigenvector solution is used; otherwise, regular EGA is used. This method was used in the Christensen et al.'s (2023) <i>Behavior Research</i> <i>Methods</i> simulation
	 "louvain" — Applies the Louvain algorithm (cluster_louvain) on the empirical correlation matrix. If the number of dimensions is 1, then the Louvain solution is used; otherwise, regular EGA is used. This method was validated Christensen's (2022) <i>PsyArXiv</i> simulation. Consensus clustering can be used by specifying either "consensus.method" or "consensus.iter"

iter	Numeric (length = 1). Number of replica samples to generate from the bootstrap analysis. Defaults to 500 (recommended)	
type	Character (length = 1). What type of bootstrap should be performed? Defaults to "parametric". Available options:	
	 "parametric" — Generates iter new datasets from (multivariate normal random distributions) based on the original dataset using myrnorm 	
	 "resampling" — Generates iter new datasets from random subsamples of the original data 	
ncores	Numeric (length = 1). Number of cores to use in computing results. Defaults to ceiling(parallel::detectCores() / 2) or half of your computer's process- ing power. Set to 1 to not use parallel computing	
	If you're unsure how many cores your computer has, then type: parallel::detectCores()	
EGA.type	Character (length = 1). Type of EGA model to use. Defaults to "EGA" Available options:	
	• "EGA" — Uses standard exploratory graph analysis	
	• "EGA.fit" — Uses tefi to determine best fit of EGA	
	• "hierEGA" — Uses hierarchical exploratory graph analysis	
	 "riEGA" — Uses random-intercept exploratory graph analysis 	
	Arguments for EGA.type can be added (see links for details on specific function arguments)	
plot.itemStabi	lity	
	Boolean (length = 1). Should the plot be produced for item.replication? Defaults to TRUE	
typicalStructu	re	
	Boolean (length = 1). If TRUE, returns the median ("glasso" or "BGGM") or mean ("TMFG") network structure and estimates its dimensions (see Details for more information). Defaults to FALSE	
plot.typicalStructure		
	Boolean (length = 1). If TRUE, returns a plot of the typical network structure. Defaults to FALSE	
seed	Numeric (length = 1). Defaults to NULL or random results. Set for reproducible results. See Reproducibility and PRNG for more details on random number generation in EGAnet	
verbose	Boolean (length = 1). Should progress be displayed? Defaults to TRUE. Set to FALSE to not display progress	
	Additional arguments that can be passed on to auto.correlate, network.estimation, community.detection, community.consensus, EGA, EGA.fit, hierEGA, and riEGA	

Details

The typical network structure is derived from the median (or mean) value of each pairwise relationship. These values tend to reflect the "typical" value taken by an edge across the bootstrap networks. Afterward, the same community detection algorithm is applied to the typical network as the bootstrap networks. Because the community detection algorithm is applied to the typical network structure, there is a possibility that the community algorithm determines a different number of dimensions than the median number derived from the bootstraps. The typical network structure (and number of dimensions) may *not* match the empirical EGA number of dimensions or the median number of dimensions from the bootstrap. This result is known and *not* a bug.

Value

Returns a list containing:

iter	Number of replica samples in bootstrap
bootGraphs	A list containing the networks of each replica sample
bootCorrs	A list containing the zero-order correlations of each replica sample
boot.wc	A matrix of membership assignments for each replica network with variables down the columns and replicas across the rows
boot.ndim	Number of dimensions identified in each replica sample
summary.table	A data frame containing number of replica samples, median, standard deviation, standard error, 95% confidence intervals, and quantiles (lower = 2.5% and upper = 97.5%)
frequency	A data frame containing the proportion of times the number of dimensions was identified (e.g., .85 of 1,000 = 850 times that specific number of dimensions was found)
TEFI	tefi value for each replica sample
type	Type of bootstrap used
EGA	Output of the empirical EGA results (output will vary based on EGA.type)
EGA.type	Type of *EGA function used
typicalGraph	A list containing:
	 graph — Network matrix of the median network structure
	 typical.dim.variables — An ordered matrix of item allocation
	 wc — Membership assignments of the median network
plot.typical.e	ga
	Plot output if plot.typicalStructure = TRUE

)
## End(Not run)
```

Description

Verifies the fit of the structure suggested by EGA or by hierEGA using confirmatory factor analysis

Usage

```
CFA(ega.obj, data, estimator, plot.CFA = TRUE, layout = "spring", ...)
```

Arguments

ega.obj	An EGA object or an hierEGA
data	Matrix or data frame. Should consist only of variables to be used in the analysis
estimator	The estimator used in the confirmatory factor analysis. 'WLSMV' is the esti- mator of choice for ordinal variables. 'ML' or 'WLS' for interval variables. See lavOptions for more details
plot.CFA	Logical. Should the CFA structure with its standardized loadings be plot? Defaults to TRUE $% \mathcal{A}_{\mathrm{TRUE}}$
layout	Layout of plot (see semPaths). Defaults to "spring"
	Arguments passed to cfa

Value

Returns a list containing:

fit	Output from cfa
summary	Summary output from lavaan-class
fit.measures	Fit measures: chi-squared, degrees of freedom, p-value, CFI, RMSEA, GFI, and NFI. Additional fit measures can be applied using the fitMeasures function (see examples)

color_palette_EGA

Examples

```
# Load data
wmt <- wmt2[,7:24]</pre>
## Not run:
# Estimate EGA
ega.wmt <- EGA(
  data = wmt,
  plot.EGA = FALSE # No plot for CRAN checks
)
# Fit CFA model to EGA results
cfa.wmt <- CFA(
  ega.obj = ega.wmt, estimator = "WLSMV",
  plot.CFA = FALSE, # No plot for CRAN checks
  data = wmt
)
# Additional fit measures
lavaan::fitMeasures(cfa.wmt$fit, fit.measures = "all")
## End(Not run)
```

color_palette_EGA EGA Color Palettes

Description

Color palettes for plotting ggnet2 EGA network plots

Usage

```
color_palette_EGA(
  name = c("polychrome", "blue.ridge1", "blue.ridge2", "rainbow", "rio", "itacare",
      "grayscale"),
   wc,
   sorted = FALSE
)
```

Arguments

name

Character. Name of color scheme (see RColorBrewer). Defaults to "polychrome". EGA palettes:

- "polychrome" Default 40 color palette
- "grayscale" "grayscale", "greyscale", or "colorblind" will produce plots suitable for publication purposes
- "blue.ridge1" Palette inspired by the Blue Ridge Mountains
- "blue.ridge2" Second palette inspired by the Blue Ridge Mountains

	 "rainbow" — Rainbow colors. Default for qgraph
	 "rio" — Palette inspired by Rio de Janiero, Brazil
	• "itacare" — Palette inspired by Itacare, Brazil
	For custom colors, enter HEX codes for each dimension in a vector
wc	Numeric vector. A vector representing the community (dimension) membership of each node in the network. NA values mean that the node was disconnected from the network
sorted	Boolean. Should colors be sorted by wc? Defaults to FALSE

Value

Vector of colors for community memberships

Author(s)

Hudson Golino <hfg9s at virginia.edu>, Alexander P. Christensen <alexpaulchristensen at gmail.com>

```
# Default
color_palette_EGA(name = "polychrome", wc = ega.wmt$wc)
# Blue Ridge Moutains 1
color_palette_EGA(name = "blue.ridge1", wc = ega.wmt$wc)
# Custom
color_palette_EGA(name = c("#7FD1B9", "#24547e"), wc = ega.wmt$wc)
```

community.compare Compares Community Detection Solutions Using Permutation

Description

A permutation implementation to determine statistical significance of whether the community comparison measure is different from zero

community.compare

Usage

```
community.compare(
  base,
  comparison,
  method = c("vi", "nmi", "split.join", "rand", "adjusted.rand"),
  iter = 1000,
  shuffle.base = TRUE,
  verbose = TRUE,
  seed = NULL
)
```

Arguments

base	Character or numeric vector. A vector of characters or numbers that are treated as the baseline communities
comparison	Character or numeric vector (length = length(base)). A vector of characters or numbers that are treated as the baseline communities
method	Character (length = 1). Comparison metrics from compare. Defaults to "adjusted.rand" Available options:
	 "vi" — Variation of information (Meila, 2003) "nmi" — Normalized mutual information (Danon et al., 2003)
	• "split.join" — Split-join distance (Dongen, 2000)
	• "rand" — Rand index (Rand, 1971)
	 "adjusted.rand" — adjusted Rand index (Hubert & Arabie, 1985; Stein- ley, 2004)
iter	Numeric (length = 1). Number of permutations to perform. Defaults to 1000 (recommended)
shuffle.base	Boolean (length = 1). Whether the base cluster solution should be shuffled. Defaults to TRUE to remain consistent with original implementation (Qannari et al., 2014); however, from a theoretical standpoint, it might make sense to only shuffle the comparison to determine whether it is specifically different from the recognized base
verbose	Boolean (length = 1). Should progress be displayed? Defaults to TRUE. Set to FALSE to not display progress
seed	Numeric (length = 1). Defaults to NULL or random results. Set for reproducible results. See Reproducibility and PRNG for more details on random number generation in EGAnet

Value

Returns data frame containing method used (Method), empirical or observed value (Empirical), and p-value based on the permutation test (p.value)

Author(s)

Hudson Golino <hfg9s at virginia.edu> and Alexander P. Christensen <alexpaulchristensen@gmail.com>

edge_between <- community.detection(network, algorithm = "edge_betweenness")
# Compute Fast Greedy
fast_greedy <- community.detection(network, algorithm = "fast_greedy")
# Perform permutation test</pre>
```

```
community.compare(edge_between, fast_greedy)
```

community.consensus Applies the Consensus Clustering Method (Louvain only)

Description

Applies the consensus clustering method introduced by (Lancichinetti & Fortunato, 2012). The original implementation of this method applies a community detection algorithm repeatedly to the same network. With stochastic networks, the algorithm is likely to identify different community solutions with many repeated applications.

Usage

```
community.consensus(
    network,
    order = c("lower", "higher"),
    resolution = 1,
    consensus.method = c("highest_modularity", "iterative", "most_common", "lowest_tefi"),
    consensus.iter = 1000,
    correlation.matrix = NULL,
    allow.singleton = FALSE,
    membership.only = TRUE,
    ...
)
```

Arguments

network	Matrix or igraph network object
order	Character (length = 1). Defaults to "higher". Whether "lower" or "higher" order memberships from the Louvain algorithm should be obtained for the consensus. The "lower" order Louvain memberships are from the first initial pass of the Louvain algorithm whereas the "higher" order Louvain memberships are from the last pass of the Louvain algorithm
resolution	Numeric (length = 1). A parameter that adjusts modularity to allow the algorithm to prefer smaller (resolution > 1) or larger ($0 < \text{resolution} < 1$) communities. Defaults to 1 (standard modularity computation)
consensus.meth	od
	Character (length = 1). Defaults to "most_common". Available options for arriving at a consensus (<i>Note</i> : All methods except "iterative" are considered experimental until validated):
	• "highest_modularity" — EXPERIMENTAL. Selects the community solution with the highest modularity across the applications. Modularity is a reasonable metric for identifying the number of communities in a network but it comes with limitations (e.g., resolution limit)
	• "iterative" — The original approach proposed by Lancichinetti & For- tunato (2012). See "Details" for more information
	• "most_common" — Selects the community solution that appears the most frequently across the applications. The idea behind this method is that the solution that appears most often will be the most likely solution for the algorithm as well as most reproducible. Can be less stable as the number of nodes increase requiring a larger value for consensus.iter. This method is the default

- "lowest_tefi" EXPERIMENTAL. Selects the community solution with the lowest Total Entropy Fit Index (tefi) across the applications. TEFI is a reasonable metric to identify the number of communities in a network based on Golino, Moulder et al. (2020)
- consensus.iter Numeric (length = 1). Number of algorithm applications to the network. Defaults to 1000

correlation.matrix

Symmetric matrix. Used for computation of tefi. Only needed when consensus.method = "tefi"

allow.singleton

Boolean (length = 1). Whether singleton or single node communities should be allowed. Defaults to FALSE. When FALSE, singleton communities will be set to missing (NA); otherwise, when TRUE, singleton communities will be allowed

membership.only

Boolean. Whether the memberships only should be output. Defaults to TRUE.Set to FALSE to obtain all output for the community detection algorithm

... Not actually used but makes it easier for general functionality in the package

Details

The goal of the consensus clustering method is to identify a stable solution across algorithm applications to derive a "consensus" clustering. The standard or "iterative" approach is to apply the community detection algorithm N times. Then, a co-occurrence matrix is created representing how often each pair of nodes co-occurred across the applications. Based on some cut-off value (e.g., 0.30), co-occurrences below this value are set to zero, forming a "new" sparse network. The procedure proceeds until all nodes co-occur with all other nodes in their community (or a proportion of 1.00).

Variations of this procedure are also available in this package but are **experimental**. Use these experimental procedures with caution. More work is necessary before these experimental procedures are validated

At this time, seed setting for consensus clustering is not supported

Value

Returns either a vector with the selected solution or a list when membership.only = FALSE:

selected_solu	tion
	Resulting solution from the consensus method
memberships	Matrix of memberships across the consensus iterations
proportion_ta	ble
	For methods that use frequency, a table that reports those frequencies alongside
	their corresponding memberships

  consensus.method = "lowest_tefi",
  correlation.matrix = correlation.matrix
)
```

community.detection Apply a Community Detection Algorithm

Description

General function to apply community detection algorithms available in igraph. Follows the EGAnet approach of setting singleton and disconnected nodes to missing (NA)

Usage

```
community.detection(
   network,
   algorithm = c("edge_betweenness", "fast_greedy", "fluid", "infomap", "label_prop",
        "leading_eigen", "leiden", "louvain", "optimal", "spinglass", "walktrap"),
   allow.singleton = FALSE,
   membership.only = TRUE,
   ...
)
```

Arguments

network	Matrix or igraph network object
algorithm	Character or igraph cluster_* function (length = 1). Available options:
	 "edge_betweenness" — See cluster_edge_betweenness for more de- tails
	 "fast_greedy" — See cluster_fast_greedy for more details
	 "fluid" — See cluster_fluid_communities for more details
	 "infomap" — See cluster_infomap for more details
	 "label_prop" — See cluster_label_prop for more details
	 "leading_eigen" — See cluster_leading_eigen for more details
	 "leiden" — See cluster_leiden for more details. Note: The Leiden al- gorithm will default to the modularity objective function (objective_function = "modularity"). Set objective_function = "CPM" to use the Constant Potts Model instead (see examples)
	• "louvain" — See cluster_louvain for more details
	 "optimal" — See cluster_optimal for more details
	 "spinglass" — See cluster_spinglass for more details
	 "walktrap" — See cluster_walktrap for more details
allow.singleto	n
	Boolean (length = 1). Whether singleton or single node communities should be allowed. Defaults to FALSE. When FALSE, singleton communities will be set to missing (NA); otherwise, when TRUE, singleton communities will be allowed
membership.onl	у
	Boolean (length = 1). Whether the memberships only should be output. Defaults to TRUE. Set to FALSE to obtain all output for the community detection algorithm

community.detection

... Additional arguments to be passed on to igraph's community detection functions (see algorithm for link to arguments of each algorithm)

Value

Returns memberships from a community detection algorithm

Author(s)

Hudson Golino <hfg9s at virginia.edu> and Alexander P. Christensen <alexpaulchristensen@gmail.com>

  objective_function = "modularity"
)
# Compute Leiden (with CPM)
```

```
community.detection(
 network, algorithm = "leiden",
 objective_function = "CPM",
 resolution_parameter = 0.05 # "edge density"
)
# Compute Louvain
community.detection(network, algorithm = "louvain")
# Compute Optimal (identifies maximum modularity solution)
community.detection(network, algorithm = "optimal")
# Compute Spinglass
community.detection(network, algorithm = "spinglass")
# Compute Walktrap
community.detection(network, algorithm = "walktrap")
# Example with {igraph} network
community.detection(
 convert2igraph(network), algorithm = "walktrap"
)
```

community.homogenize Homogenize Community Memberships

Description

Memberships from community detection algorithms do not always align numerically. This function seeks to homogenize community memberships between a target membership (the membership to homogenize toward) and one or more other memberships. This function is the core of the dimensionStability and itemStability functions

Usage

community.homogenize(target.membership, convert.membership)

Arguments

target.membership

Vector, matrix, or data frame. The target memberships that all other memberships input into convert.membership should be homogenize **toward**

convert.membership

Vector, matrix, or data frame. Either a vector of memberships the same length as target.membership or a matrix or data frame of many membership solutions with either across rows or down columns the same length as target.membership (this function will automatically determine this orientation for you with precedence given solutions *across rows*)

Value

Returns a vector or matrix the length or size of convert.membership with memberships homogenized toward target.membership

Author(s)

Hudson Golino <hfg9s at virginia.edu> and Alexander P. Christensen <alexpaulchristensen@gmail.com>

    network, algorithm = "louvain"
)
# Homogenize toward Walktrap
community.homogenize(network_walktrap, network_louvain)</pre>
```

community.unidimensional

Approaches to Detect Unidimensional Communities

Description

A function to apply several approaches to detect a unidimensional community in networks. There have many different approaches recently such as expanding the correlation matrix to have orthogonal correlations ("expand"), applying the Leading Eigenvalue community detection algorithm cluster_leading_eigen to the correlation matrix ("LE"), and applying the Louvain community detection algorithm cluster_louvain to the correlation matrix ("louvain"). Not necessarily intended for individual use – it's better to use EGA

Usage

```
community.unidimensional(
   data,
   n = NULL,
   corr = c("auto", "cor_auto", "pearson", "spearman"),
   na.data = c("pairwise", "listwise"),
   model = c("BGGM", "glasso", "TMFG"),
   uni.method = c("expand", "LE", "louvain"),
   verbose = FALSE,
   ...
)
```

Arguments

data	Matrix or data frame. Should consist only of variables that are desired to be in analysis
n	Numeric (length = 1). Sample size if data provided is a correlation matrix
corr	Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:
	• "auto" — Automatically computes appropriate correlations for the data us- ing Pearson's for continuous, polychoric for ordinal, tetrachoric for binary, and polyserial/biserial for ordinal/binary with continuous. To change the number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details)
	• "cor_auto" — Uses cor_auto to compute correlations. Arguments can be passed along to the function
	• "pearson" — Pearson's correlation is computed for all variables regardless of categories
	 "spearman" — Spearman's rank-order correlation is computed for all vari- ables regardless of categories
	For other similarity measures, compute them first and input them into data with the sample size (n)
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
	• "pairwise" — Computes correlation for all available cases between two variables
	• "listwise" — Computes correlation for all complete cases in the dataset
model	Character (length = 1). Defaults to "glasso". Available options:
	• "BGGM" — Computes the Bayesian Gaussian Graphical Model. Set argument ordinal.categories to determine levels allowed for a variable to be considered ordinal. See ?BGGM::estimate for more details
	• "glasso" — Computes the GLASSO with EBIC model selection. See EBICglasso.qgraph for more details

- "TMFG" — Computes the TMFG method. See TMFG for more details

uni.method	Character (length = 1). What unidimensionality method should be used? De- faults to "louvain". Available options:
	• "expand" — Expands the correlation matrix with four variables correlated 0.50. If number of dimension returns 2 or less in check, then the data are unidimensional; otherwise, regular EGA with no matrix expansion is used. This method was used in the Golino et al.'s (2020) <i>Psychological Methods</i> simulation
	 "LE" — Applies the Leading Eigenvector algorithm (cluster_leading_eigen) on the empirical correlation matrix. If the number of dimensions is 1, then the Leading Eigenvector solution is used; otherwise, regular EGA is used. This method was used in the Christensen et al.'s (2023) <i>Behavior Research Methods</i> simulation
	• "louvain" — Applies the Louvain algorithm (cluster_louvain) on the empirical correlation matrix. If the number of dimensions is 1, then the Louvain solution is used; otherwise, regular EGA is used. This method was validated Christensen's (2022) <i>PsyArXiv</i> simulation. Consensus clustering can be used by specifying either "consensus.method" or "consensus.iter"
verbose	Boolean. Whether messages and (insignificant) warnings should be output. De- faults to FALSE (silent calls). Set to TRUE to see all messages and warnings for every function call
	Additional arguments to be passed on to auto.correlate, network.estimation, community.consensus, and community.detection

Value

Returns the memberships of the community detection algorithm. The memberships will output regardless of whether the network is unidimensional

Author(s)

Hudson Golino <hfg9s at virginia.edu> and Alexander P. Christensen <alexpaulchristensen@gmail.com>

References

Expand approach

Louvain approach

Christensen, A. P. (2023). Unidimensional community detection: A Monte Carlo simulation, grid search, and comparison. PsyArXiv.

Examples

```
# Load data
wmt <- wmt2[,7:24]
# Louvain with Consensus Clustering (default)
community.unidimensional(wmt)
# Leading Eigenvector
community.unidimensional(wmt, uni.method = "LE")
# Expand
community.unidimensional(wmt, uni.method = "expand")</pre>
```

compare.EGA.plots Visually Compare Two or More EGAnet plots

Description

Organizes EGA plots for comparison. Ensures that nodes are placed in the same layout to maximize comparison

Usage

```
compare.EGA.plots(
    ...,
    input.list = NULL,
    base = 1,
    labels = NULL,
    rows = NULL,
    columns = NULL,
    plot.all = TRUE
)
```

Arguments

	Handles multiple arguments:
	• *EGA objects — can be dropped in without any argument designation. The function will search across input to find necessary EGAnet objects
	 ggnet2 arguments — can be passed along to ggnet2
	• gplot.layout — can be specified using mode = or layout = using the name of the layout (e.g., mode = "circle" will produce the circle layout from gplot.layout). By default, the layout is the same as qgraph
input.list	List. Bypasses argument in favor of using a list as an input
base	Numeric (length = 1). Plot to be used as the base for the configuration of the networks. Uses the number of the order in which the plots are input. Defaults to 1 or the first plot

labels	Character (same length as input). Labels for each EGAnet object
rows	Numeric (length = 1). Number of rows to spread plots across
columns	Numeric (length = 1). Number of columns to spread plots down
plot.all	Boolean (length = 1). Whether plot should be produced or just output. Defaults to TRUE. Set to FALSE to avoid plotting (but still obtain plot objects)

Value

Visual comparison of EGAnet objects

Author(s)

Alexander Christensen <alexpaulchristensen@gmail.com>

See Also

plot.EGAnet for plot usage in EGAnet

Examples

```
# Obtain WMT-2 data
wmt <- wmt2[,7:24]</pre>
# Draw random samples of 300 cases
sample1 <- wmt[sample(1:nrow(wmt), 300),]</pre>
sample2 <- wmt[sample(1:nrow(wmt), 300),]</pre>
# Estimate EGAs
ega1 <- EGA(sample1)</pre>
ega2 <- EGA(sample2)</pre>
# Compare EGAs via plot
compare.EGA.plots(
  ega1, ega2,
  base = 1, # use "ega1" as base for comparison
  labels = c("Sample 1", "Sample 2"),
  rows = 1, columns = 2
)
# Change layout to circle plots
compare.EGA.plots(
  ega1, ega2,
  labels = c("Sample 1", "Sample 2"),
  mode = "circle"
)
```

convert2igraph

Description

Converts networks to igraph format

Usage

```
convert2igraph(A, diagonal = 0)
```

Arguments

Α	Matrix or data frame. $N \ge N$ matrix where N is the number of nodes
diagonal	Numeric. Value to be placed on the diagonal of A. Defaults to 0

Value

Returns a network in the igraph format

Author(s)

Hudson Golino <hfg9s at virginia.edu> & Alexander P. Christensen <alexander.christensen at Vanderbilt.Edu>

Examples

convert2igraph(ega.wmt\$network)

convert2tidygraph Convert networks to tidygraph

Description

Converts networks to tidygraph format

Usage

```
convert2tidygraph(EGA.object)
```

Arguments

EGA.object A single EGAnet object containing the outputs \$network and \$wc

cosine

Value

Returns a network in the tidygraph format

Author(s)

Dominique Makowski, Hudson Golino <hfg9s at virginia.edu>, & Alexander P. Christensen <alexander.christensen at Vanderbilt.Edu>

Examples

```
convert2tidygraph(ega.wmt)
```

cosine

Cosine similarity

Description

Computes cosine similarity

Usage

cosine(x, y = NULL, ...)

Arguments

х	Numeric vector, matrix, or data frame. If $nrow(x) > 1$, then x will be treated as a matrix to compute an <i>n</i> by <i>n</i> similarity matrix (y will not be used!)
У	Numeric vector, matrix, or data frame. Only used if x is a single variable. Used to compute similarity between one variable and n other variables. Defaults to NULL
	Not actually used but makes it easier for general functionality in the package

Details

On missing values: 0 will be used to replace missing values. When using (matrix) multiplication, the 0 value cancels out the product rendering the missing value as "not counting" in the sums

Author(s)

Alexander P. Christensen <alexpaulchristensen@gmail.com>

Examples

```
# Load data
wmt <- wmt2[,7:24]
# Obtain cosines
wmt_cosine <- cosine(wmt)</pre>
```

depression

Depression Data

Description

A response matrix (n = 574) of the Beck Depression Inventory, Beck Anxiety Inventory, and the Athens Insomnia Scale.

Usage

data(depression)

Format

A 574x78 response matrix

Examples

data("depression")

dimensionStability Dimension Stability Statistics from bootEGA

Description

Based on the bootEGA results, this function computes the stability of dimensions. Stability is computed by assessing the proportion of times the original dimension is exactly replicated in across bootstrap samples

Usage

```
dimensionStability(bootega.obj, IS.plot = TRUE, structure = NULL, ...)
```

dimensionStability

Arguments

bootega.obj	A bootEGA object
IS.plot	Boolean (length = 1). Should the plot be produced for item.replication? Defaults to TRUE
structure	Numeric (length = number of variables). A theoretical or pre-defined structure. Defaults to NULL or the empirical EGA result in the bootega.obj
	Additional arguments. Used for deprecated arguments from previous versions of itemStability

Value

Returns a list containing:

dimension.stability

A list containing:

- structural.consistency The proportion of times that each empirical EGA dimension *exactly* replicates across the bootEGA samples
- average.item.stability The average item stability in each empirical EGA dimension

item.stability Results from itemStability

Author(s)

Conceptual introduction

Christensen, A. P., Golino, H., & Silvia, P. J. (2020). A psychometric network perspective on the validity and validation of personality trait questionnaires. *European Journal of Personality*, *34*(6), 1095-1108.

Examples

```
# Load data
wmt <- wmt2[,7:24]
## Not run:
# Estimate bootstrap EGA
boot.wmt <- bootEGA(
   data = wmt, iter = 500,
   type = "parametric", ncores = 2
)
## End(Not run)</pre>
```

```
# Estimate stability statistics
dimensionStability(boot.wmt)
```

dnn.weights

Loadings Comparison Test Deep Learning Neural Network Weights

Description

A list of weights from four different neural network models: random vs. non-random model (r_nr_weights), low correlation factor vs. network model (lf_n_weights), high correlation with variables less than or equal to factors vs. network model (hlf_n_weights), and high correlation with variables greater than factors vs. network model (hgf_n_weights)

Usage

```
data(dnn.weights)
```

Format

A list of with a length of 4

Examples

data("dnn.weights")

dynEGA

Dynamic Exploratory Graph Analysis

Description

Estimates dynamic communities in multivariate time series (e.g., panel data, longitudinal data, intensive longitudinal data) at multiple time scales and at different levels of analysis: individuals (intraindividual structure), groups, and population (interindividual structure)

Usage

```
dynEGA(
   data,
   id = NULL,
   group = NULL,
   n.embed = 5,
   tau = 1,
   delta = 1,
   use.derivatives = 1,
```
dynEGA

```
level = c("individual", "group", "population"),
corr = c("auto", "cor_auto", "pearson", "spearman"),
na.data = c("pairwise", "listwise"),
model = c("BGGM", "glasso", "TMFG"),
algorithm = c("leiden", "louvain", "walktrap"),
uni.method = c("expand", "LE", "louvain"),
ncores,
verbose = TRUE,
...
```

Arguments

)

data	Matrix or data frame. Participants and variable should be in long format such that row <i>t</i> represents observations for all variables at time point <i>t</i> for a participant. The next row, $t + 1$, represents the next measurement occasion for that same participant. The next participant's data should immediately follow, in the same pattern, after the previous participant data should have an ID variable labeled "ID"; otherwise, it is assumed that the data represent the population	
	For groups, data should have a Group variable labeled "Group"; otherwise, it is assumed that there are no groups in data	
	Arguments id and group can be specified to tell the function which column in data it should use as the ID and Group variable, respectively	
	A measurement occasion variable is not necessary and should be <i>removed</i> from the data before proceeding with the analysis	
id	Numeric or character (length = 1). Number or name of the column identifying each individual. Defaults to NULL	
group	Numeric or character (length = 1). Number of the column identifying group membership. Defaults to NULL	
n.embed	Numeric (length = 1). Defaults to 5. Number of embedded dimensions (the number of observations to be used in the Embed function). For example, an "n.embed = 5" will use five consecutive observations to estimate a single derivative	
tau	Numeric (length = 1). Defaults to 1. Number of observations to offset successive embeddings in the Embed function. Generally recommended to leave "as is"	
delta	Numeric (length = 1). Defaults to 1. The time between successive observations in the time series (i.e, lag). Generally recommended to leave "as is"	
use.derivatives		
	Numeric (length = 1). Defaults to 1. The order of the derivative to be used in the analysis. Available options:	
	• 0 — No derivatives; consistent with moving average	
	• 1 — First-order derivatives; interpreted as "velocity" or rate of change over time	
	• 2 — Second-order derivatives; interpreted as "acceleration" or rate of the rate of change over time	

	Generally recommended to leave "as is"
level	Character vector (up to length of 3). A character vector indicating which level(s) to estimate:
	• "individual" — Estimates EGA for each individual in data (intraindivid- ual structure; requires an "ID" column, see data)
	• "group" — Estimates EGA for each group in data (group structure; requires a "Group" column, see data)
	• "population" — Estimates EGA across all data (interindividual structure)
corr	Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:
	• "auto" — Automatically computes appropriate correlations for the data us- ing Pearson's for continuous, polychoric for ordinal, tetrachoric for binary, and polyserial/biserial for ordinal/binary with continuous. To change the number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details)
	• "cor_auto" — Uses cor_auto to compute correlations. Arguments can be passed along to the function
	• "pearson" — Pearson's correlation is computed for all variables regardless of categories
	 "spearman" — Spearman's rank-order correlation is computed for all vari- ables regardless of categories
	For other similarity measures, compute them first and input them into data with the sample size (n)
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
	• "pairwise" — Computes correlation for all available cases between two variables
	• "listwise" — Computes correlation for all complete cases in the dataset
model	Character (length = 1). Defaults to "glasso". Available options:
	 "BGGM" — Computes the Bayesian Gaussian Graphical Model. Set argument ordinal.categories to determine levels allowed for a variable to be considered ordinal. See ?BGGM::estimate for more details "glasso" — Computes the GLASSO with EBIC model selection. See
	 EBICglasso. qgraph for more details "TMFG" — Computes the TMFG method. See TMFG for more details
algorithm	Character or igraph cluster_* function (length = 1). Defaults to "walktrap". Three options are listed below but all are available (see community.detection for other options):
	 "leiden" — See cluster_leiden for more details "louvain" — By default, "louvain" will implement the Louvain algorithm using the consensus clustering method (see community.consensus for more information). This function will implement consensus.method = "most_common" and consensus.iter = 1000 unless specified otherwise

	 "walktrap" — See cluster_walktrap for more details
uni.method	Character (length = 1). What unidimensionality method should be used? De- faults to "louvain". Available options:
	 "expand" — Expands the correlation matrix with four variables correlated 0.50. If number of dimension returns 2 or less in check, then the data are unidimensional; otherwise, regular EGA with no matrix expansion is used. This method was used in the Golino et al.'s (2020) <i>Psychological Methods</i> simulation
	 "LE" — Applies the Leading Eigenvector algorithm (cluster_leading_eigen) on the empirical correlation matrix. If the number of dimensions is 1, then the Leading Eigenvector solution is used; otherwise, regular EGA is used. This method was used in the Christensen et al.'s (2023) <i>Behavior Research</i> <i>Methods</i> simulation
	 "louvain" — Applies the Louvain algorithm (cluster_louvain) on the empirical correlation matrix. If the number of dimensions is 1, then the Louvain solution is used; otherwise, regular EGA is used. This method was validated Christensen's (2022) <i>PsyArXiv</i> simulation. Consensus clustering can be used by specifying either "consensus.method" or "consensus.iter"
ncores	Numeric (length = 1). Number of cores to use in computing results. Defaults to ceiling(parallel::detectCores() / 2) or half of your computer's process- ing power. Set to 1 to not use parallel computing If you're unsure how many cores your computer has then type: parallel::detectCores()
verbose	Boolean (length = 1). Should progress be displayed? Defaults to TRUE. Set to FALSE to not display progress
	Additional arguments to be passed on to auto.correlate, network.estimation, community.detection, community.consensus, and EGA

Details

Derivatives for each variable's time series for each participant are estimated using generalized local linear approximation (see glla). EGA is then applied to these derivatives to model how variables are changing together over time. Variables that change together over time are detected as communities

Value

A list containing:

Derivatives	A list containing:
	• Estimates — A list the length of the unique IDs containing data frames of zero- to second-order derivatives for each ID in data
	• EstimatesDF — A data frame of derivatives across all IDs containing columns of the zero- to second-order derivatives as well as id and group variables (group is automatically set to 1 for all if no group is provided)
dynEGA	A list containing:
	• population — If level includes "populaton", then the EGA results for the entire sample

- group If level includes "group", then a list containing the EGA results for each group
- individual If level includes "individual", then a list containing the EGA results for each id

dynEGA.ind.pop Intra- and Inter-individual dynEGA

Description

A wrapper function to estimate both intraindividual (level = "individual") and interindividual (level = "population") structures using dynEGA

Usage

```
dynEGA.ind.pop(
   data,
   id = NULL,
   n.embed = 5,
   tau = 1,
   delta = 1,
   use.derivatives = 1,
   corr = c("auto", "cor_auto", "pearson", "spearman"),
   na.data = c("pairwise", "listwise"),
   model = c("BGGM", "glasso", "TMFG"),
```

```
algorithm = c("leiden", "louvain", "walktrap"),
uni.method = c("expand", "LE", "louvain"),
ncores,
verbose = TRUE,
...
```

Arguments

data	Matrix or data frame. Participants and variable should be in long format such that row t represents observations for all variables at time point t for a participant. The next row, $t + 1$, represents the next measurement occasion for that same participant. The next participant's data should immediately follow, in the same pattern, after the previous participant
	data should have an ID variable labeled "ID"; otherwise, it is assumed that the data represent the population
	For groups, data should have a Group variable labeled "Group"; otherwise, it is assumed that there are no groups in data
	Arguments id and group can be specified to tell the function which column in data it should use as the ID and Group variable, respectively
	A measurement occasion variable is not necessary and should be <i>removed</i> from the data before proceeding with the analysis
id	Numeric or character (length = 1). Number or name of the column identifying each individual. Defaults to NULL
n.embed	Numeric (length = 1). Defaults to 5. Number of embedded dimensions (the number of observations to be used in the Embed function). For example, an "n.embed = 5" will use five consecutive observations to estimate a single derivative
tau	Numeric (length = 1). Defaults to 1. Number of observations to offset successive embeddings in the Embed function. Generally recommended to leave "as is"
delta	Numeric (length = 1). Defaults to 1. The time between successive observations in the time series (i.e, lag). Generally recommended to leave "as is"
use.derivatives	5
	Numeric (length = 1). Defaults to 1. The order of the derivative to be used in the analysis. Available options:
	• 0 — No derivatives; consistent with moving average
	• 1 — First-order derivatives; interpreted as "velocity" or rate of change over time
	• 2 — Second-order derivatives; interpreted as "acceleration" or rate of the rate of change over time
	Generally recommended to leave "as is"
corr	Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:
	• "auto" — Automatically computes appropriate correlations for the data us- ing Pearson's for continuous, polychoric for ordinal, tetrachoric for binary,

42

	and polyserial/biserial for ordinal/binary with continuous. To change the number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details)
	 "cor_auto" — Uses cor_auto to compute correlations. Arguments can be passed along to the function
	 "pearson" — Pearson's correlation is computed for all variables regardless of categories
	 "spearman" — Spearman's rank-order correlation is computed for all vari- ables regardless of categories
	For other similarity measures, compute them first and input them into data with the sample size (n)
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
	 "pairwise" — Computes correlation for all available cases between two variables
	• "listwise" — Computes correlation for all complete cases in the dataset
model	Character (length = 1). Defaults to "glasso". Available options:
	 "BGGM" — Computes the Bayesian Gaussian Graphical Model. Set argument ordinal.categories to determine levels allowed for a variable to be considered ordinal. See ?BGGM::estimate for more details "glasso" — Computes the GLASSO with EBIC model selection. See EBICglasso.qgraph for more details
	• "TMFG" — Computes the TMFG method. See TMFG for more details
algorithm	Character or igraph cluster_* function (length = 1). Defaults to "walktrap". Three options are listed below but all are available (see community.detection for other options):
	 "leiden" — See cluster_leiden for more details "louvain" — By default, "louvain" will implement the Louvain algorithm using the consensus clustering method (see community.consensus for more information). This function will implement consensus.method = "most_common" and consensus.iter = 1000 unless specified otherwise
	 "walktrap" — See cluster_walktrap for more details
uni.method	Character (length = 1). What unidimensionality method should be used? Defaults to "louvain". Available options:
	 "expand" — Expands the correlation matrix with four variables correlated 0.50. If number of dimension returns 2 or less in check, then the data are unidimensional; otherwise, regular EGA with no matrix expansion is used. This method was used in the Golino et al.'s (2020) <i>Psychological Methods</i> simulation
	 "LE" — Applies the Leading Eigenvector algorithm (cluster_leading_eigen) on the empirical correlation matrix. If the number of dimensions is 1, then the Leading Eigenvector solution is used; otherwise, regular EGA is used. This method was used in the Christensen et al.'s (2023) <i>Behavior Research Methods</i> simulation

	 "louvain" — Applies the Louvain algorithm (cluster_louvain) on the empirical correlation matrix. If the number of dimensions is 1, then the Louvain solution is used; otherwise, regular EGA is used. This method was validated Christensen's (2022) <i>PsyArXiv</i> simulation. Consensus clustering can be used by specifying either "consensus.method" or "consensus.iter"
ncores	Numeric (length = 1). Number of cores to use in computing results. Defaults to ceiling(parallel::detectCores() / 2) or half of your computer's process- ing power. Set to 1 to not use parallel computing
	If you're unsure how many cores your computer has, then type: parallel::detectCores()
verbose	Boolean (length = 1). Should progress be displayed? Defaults to TRUE. Set to FALSE to not display progress
	Additional arguments to be passed on to auto.correlate, network.estimation, community.detection, community.consensus, and EGA

Value

Same output as EGAnet{dynEGA} returning list objects for level = "individual" and level = "population"

Author(s)

Hudson Golino <hfg9s at virginia.edu>

plot.EGAnet for plot usage in EGAnet

Examples

```
# Obtain data
sim.dynEGA <- sim.dynEGA # bypasses CRAN checks
## Not run:
# Dynamic EGA individual and population structure
dyn.ega1 <- dynEGA.ind.pop(
   data = sim.dynEGA, n.embed = 5, tau = 1,
   delta = 1, id = 25, use.derivatives = 1,
   ncores = 2, corr = "pearson"
)
## End(Not run)</pre>
```

Description

This function uses the glasso package (Friedman, Hastie and Tibshirani, 2011) to compute a sparse gaussian graphical model with the graphical lasso (Friedman, Hastie & Tibshirani, 2008). The tuning parameter is chosen using the Extended Bayesian Information criterion (EBIC) described by Foygel & Drton (2010).

Usage

```
EBICglasso.qgraph(
  data,
  n = NULL,
  corr = c("auto", "cor_auto", "cosine", "pearson", "spearman"),
  na.data = c("pairwise", "listwise"),
  gamma = 0.5,
  penalize.diagonal = FALSE,
  nlambda = 100,
  lambda.min.ratio = 0.1,
  fast = FALSE,
  returnAllResults = FALSE,
  penalizeMatrix = NULL,
  countDiagonal = FALSE,
  refit = FALSE,
 model.selection = c("EBIC", "JSD"),
  verbose = FALSE,
  . . .
)
```

Arguments

data	Matrix or data frame. Should consist only of variables to be used in the analysis
n	Numeric (length = 1). Sample size if data provided is a correlation matrix
corr	Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:
	 "auto" — Automatically computes appropriate correlations for the data using Pearson's for continuous, polychoric for ordinal, tetrachoric for binary, and polyserial/biserial for ordinal/binary with continuous. To change the number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details) "cor_auto" — Uses cor_auto to compute correlations. Arguments can be
	passed along to the function

• "cosine" — Uses cosine to compute cosine similarity

	 "pearson" — Pearson's correlation is computed for all variables regardless of categories 	
	 "spearman" — Spearman's rank-order correlation is computed for all variables regardless of categories 	
	For other similarity measures, compute them first and input them into data with the sample size (n)	
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:	
	• "pairwise" — Computes correlation for all available cases between two variables	
	• "listwise" — Computes correlation for all complete cases in the dataset	
gamma	Numeric (length = 1) EBIC tuning parameter. Defaults to 0.50 and is generally a good choice. Setting to 0 will cause regular BIC to be used	
penalize.diagor	nal	
	Boolean (length = 1). Should the diagonal be penalized? Defaults to FALSE	
nlambda	Numeric (length = 1). Number of lambda values to test. Defaults to 100	
lambda.min.rati	.0	
	Numeric (length = 1). Ratio of lowest lambda value compared to maximal lambda. Defaults to 0.1 . NOTE qgraph sets the default to 0.01	
fast	Boolean (length = 1). Whether the glassoFast version should be used to estimate the GLASSO. Defaults to FALSE.	
	The fast results <i>may</i> differ by less than floating point of the original GLASSO implemented by glasso and should not impact reproducibility much	
returnAllResult	:S	
	Boolean (length = 1). Whether all results should be returned. Defaults to FALSE (network only). Set to TRUE to access glassopath output	
penalizeMatrix	Boolean matrix. Optional logical matrix to indicate which elements are penal- ized	
countDiagonal	Boolean (length = 1). Should diagonal be counted in EBIC computation? Defaults to FALSE. Set to TRUE to mimic qgraph < 1.3 behavior (not recommended!)	
refit	Boolean (length = 1). Should the optimal graph be refitted without LASSO regularization? Defaults to FALSE	
model.selection		
	Character (length = 1). How lambda should be selected within GLASSO. De- faults to "EBIC". "JSD" is experimental and should not be used otherwise	
verbose	Boolean (length = 1). Whether messages and (insignificant) warnings should be output. Defaults to FALSE (silent calls). Set to TRUE to see all messages and warnings for every function call	
	Arguments sent to glasso	

Details

The glasso is run for 100 values of the tuning parameter logarithmically spaced between the maximal value of the tuning parameter at which all edges are zero, lambda_max, and lambda_max/100. For each of these graphs the EBIC is computed and the graph with the best EBIC is selected. The partial correlation matrix is computed using wi2net and returned.

Value

A partial correlation matrix

Author(s)

Sacha Epskamp; for maintanence, Hudson Golino <hfg9s at virginia.edu> and Alexander P. Christensen <alexander calexpaulchristensen at gmail.com>

# Compute graph with tuning = 0 (BIC)
BICgraph <- EBICglasso.qgraph(data = wmt, gamma = 0)
# Compute graph with tuning = 0.5 (EBIC)
EBICgraph <- EBICglasso.qgraph(data = wmt, gamma = 0.5)</pre>
```

Description

Estimates the number of communities (dimensions) of a dataset or correlation matrix using a network estimation method (Golino & Epskamp, 2017; Golino et al., 2020). After, a community detection algorithm is applied (Christensen et al., 2023) for multidimensional data. A unidimensional check is also applied based on findings from Golino et al. (2020) and Christensen (2023)

Usage

```
EGA(
    data,
    n = NULL,
    corr = c("auto", "cor_auto", "cosine", "pearson", "spearman"),
    na.data = c("pairwise", "listwise"),
    model = c("BGGM", "glasso", "TMFG"),
    algorithm = c("leiden", "louvain", "walktrap"),
    uni.method = c("expand", "LE", "louvain"),
    plot.EGA = TRUE,
    verbose = FALSE,
    ...
)
```

Arguments

data	Matrix or data frame. Should consist only of variables to be used in the analysis. Can be raw data or a correlation matrix
n	Numeric (length = 1). Sample size if data provided is a correlation matrix
corr	Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:
	• "auto" — Automatically computes appropriate correlations for the data us- ing Pearson's for continuous, polychoric for ordinal, tetrachoric for binary, and polyserial/biserial for ordinal/binary with continuous. To change the number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details)
	• "cor_auto" — Uses cor_auto to compute correlations. Arguments can be passed along to the function
	 "cosine" — Uses cosine to compute cosine similarity
	• "pearson" — Pearson's correlation is computed for all variables regardless of categories
	• "spearman" — Spearman's rank-order correlation is computed for all vari- ables regardless of categories

EGA

	For other similarity measures, compute them first and input them into data with the sample size (n)
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
	 "pairwise" — Computes correlation for all available cases between two variables
	• "listwise" — Computes correlation for all complete cases in the dataset
model	Character (length = 1). Defaults to "glasso". Available options:
	 "BGGM" — Computes the Bayesian Gaussian Graphical Model. Set argument ordinal.categories to determine levels allowed for a variable to be considered ordinal. See ?BGGM::estimate for more details "glasso" — Computes the GLASSO with EBIC model selection. See EBICglasso.ggraph for more details
	• "TMFG" — Computes the TMFG method. See TMFG for more details
algorithm	Character or igraph cluster_* function (length = 1). Defaults to "walktrap". Three options are listed below but all are available (see community.detection for other options):
	• "leiden" — See cluster_leiden for more details
	 "louvain" — By default, "louvain" will implement the Louvain algorithm using the consensus clustering method (see community.consensus for more information). This function will implement consensus.method = "most_common" and consensus.iter = 1000 unless specified otherwise "walktrap" — See cluster_walktrap for more details
uni.method	Character (length = 1). What unidimensionality method should be used? De- faults to "louvain". Available options:
	• "expand" — Expands the correlation matrix with four variables correlated 0.50. If number of dimension returns 2 or less in check, then the data are unidimensional; otherwise, regular EGA with no matrix expansion is used. This method was used in the Golino et al.'s (2020) <i>Psychological Methods</i> simulation
	• "LE" — Applies the Leading Eigenvector algorithm (cluster_leading_eigen) on the empirical correlation matrix. If the number of dimensions is 1, then the Leading Eigenvector solution is used; otherwise, regular EGA is used. This method was used in the Christensen et al.'s (2023) <i>Behavior Research Methods</i> simulation
	 "louvain" — Applies the Louvain algorithm (cluster_louvain) on the empirical correlation matrix. If the number of dimensions is 1, then the Louvain solution is used; otherwise, regular EGA is used. This method was validated Christensen's (2022) <i>PsyArXiv</i> simulation. Consensus clustering can be used by specifying either "consensus.method" or "consensus.iter"
plot.EGA	Boolean (length = 1). Defaults to TRUE. Whether the plot should be returned with the results. Set to FALSE for no plot
verbose	Boolean (length = 1). Whether messages and (insignificant) warnings should be output. Defaults to FALSE (silent calls). Set to TRUE to see all messages and warnings for every function call

• • •

Additional arguments to be passed on to auto.correlate, network.estimation, community.detection, community.consensus, and community.unidimensional

Value

Returns a list containing:

network	A matrix containing a network estimated using link[EGAnet]{network.estimation}
WC	A vector representing the community (dimension) membership of each node in the network. NA values mean that the node was disconnected from the network
n.dim	A scalar of how many total dimensions were identified in the network
correlation	The zero-order correlation matrix
n	Number of cases in data
dim.variables	An ordered matrix of item allocation
TEFI	link[EGAnet]{tefi} for the estimated structure
plot.EGA	Plot output if plot.EGA = TRUE

EGA.estimate

Estimates EGA for Multidimensional Structures

Description

A basic function to estimate EGA for multidimensional structures. This function does *not* include the unidimensional check and it does not plot the results. This function can be used as a streamlined approach for quick EGA estimation when unidimensionality or visualization is not a priority

Usage

```
EGA.estimate(
   data,
   n = NULL,
   corr = c("auto", "cor_auto", "cosine", "pearson", "spearman"),
   na.data = c("pairwise", "listwise"),
   model = c("BGGM", "glasso", "TMFG"),
   algorithm = c("leiden", "louvain", "walktrap"),
   verbose = FALSE,
   ...
)
```

Arguments

data	Matrix or data frame. Should consist only of variables to be used in the analysis
n	Numeric (length = 1). Sample size if data provided is a correlation matrix
corr	Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:
	 "auto" — Automatically computes appropriate correlations for the data using Pearson's for continuous, polychoric for ordinal, tetrachoric for binary, and polyserial/biserial for ordinal/binary with continuous. To change the number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details) "cor_auto" — Uses cor_auto to compute correlations. Arguments can be passed along to the function "cosine" — Uses cosine to compute cosine similarity "pearson" — Pearson's correlation is computed for all variables regardless of categories "spearman" — Spearman's rank-order correlation is computed for all variables regardless of categories
	For other similarity measures, compute them first and input them into data with the sample size (n)
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
	• "pairwise" — Computes correlation for all available cases between two variables
	• "listwise" — Computes correlation for all complete cases in the dataset
model	Character (length = 1). Defaults to "glasso". Available options:
	• "BGGM" — Computes the Bayesian Gaussian Graphical Model. Set argument ordinal.categories to determine levels allowed for a variable to be considered ordinal. See ?BGGM::estimate for more details
	• "glasso" — Computes the GLASSO with EBIC model selection. See EBICglasso.qgraph for more details
	• "TMFG" — Computes the TMFG method. See TMFG for more details

52

algorithm	Character or igraph cluster_* function (length = 1). Defaults to "walktrap". Three options are listed below but all are available (see community.detection for other options):
	 "leiden" — See cluster_leiden for more details "louvain" — By default, "louvain" will implement the Louvain algorithm using the consensus clustering method (see community.consensus for more information). This function will implement consensus.method = "most_common" and consensus.iter = 1000 unless specified otherwise "walktrap" — See cluster_walktrap for more details
verbose	Boolean (length = 1). Whether messages and (insignificant) warnings should be output. Defaults to FALSE (silent calls). Set to TRUE to see all messages and warnings for every function call
	Additional arguments to be passed on to auto.correlate, network.estimation, community.detection, and community.consensus

Value

Returns a list containing:

network	A matrix containing a network estimated using link[EGAnet]{network.estimation} % \label{eq:barrier} % \label{eq:barrier}
WC	A vector representing the community (dimension) membership of each node in the network. NA values mean that the node was disconnected from the network
n.dim	A scalar of how many total dimensions were identified in the network
cor.data	The zero-order correlation matrix
n	Number of cases in data

```

EGA.fit

EGA Optimal Model Fit using the Total Entropy Fit Index (tefi)

Description

Estimates the best fitting model using EGA. The number of steps in the cluster_walktrap detection algorithm is varied and unique community solutions are compared using tefi.

Usage

```
EGA.fit(
   data,
   n = NULL,
   corr = c("auto", "cor_auto", "cosine", "pearson", "spearman"),
   na.data = c("pairwise", "listwise"),
   model = c("BGGM", "glasso", "TMFG"),
   algorithm = c("leiden", "louvain", "walktrap"),
   plot.EGA = TRUE,
   verbose = FALSE,
   ...
)
```

Arguments

data	Matrix or data frame. Should consist only of variables to be used in the analysis
n	Numeric (length = 1). Sample size if data is a correlation matrix

54

corr	Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:
	 "auto" — Automatically computes appropriate correlations for the data using Pearson's for continuous, polychoric for ordinal, tetrachoric for binary, and polyserial/biserial for ordinal/binary with continuous. To change the number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details)
	 "cor_auto" — Uses cor_auto to compute correlations. Arguments can be passed along to the function
	 "cosine" — Uses cosine to compute cosine similarity "pearson" — Pearson's correlation is computed for all variables regardless of categories
	 "spearman" — Spearman's rank-order correlation is computed for all variables regardless of categories
	For other similarity measures, compute them first and input them into data with the sample size (n)
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
	 "pairwise" — Computes correlation for all available cases between two variables
	• "listwise" — Computes correlation for all complete cases in the dataset
model	Character (length = 1). Defaults to "glasso". Available options:
	 "BGGM" — Computes the Bayesian Gaussian Graphical Model. Set argument ordinal.categories to determine levels allowed for a variable to be considered ordinal. See ?BGGM::estimate for more details "glasso" — Computes the GLASSO with EBIC model selection. See EBICglasso.qgraph for more details
	• "TMFG" — Computes the TMFG method. See TMFG for more details
algorithm	Character or igraph cluster_* function. Three options are listed below but all are available (see community.detection for other options):
	 "leiden" — See cluster_leiden for more details. Note: The Leiden algorithm will default to the Constant Potts Model objective function (objective_function = "CPM"). Set objective_function = "modularity" to use modularity instead (see examples). By default, searches along resolutions from 0 to max(abs(network)) or the maximum absolute edge weight in the network in 0.01 increments (resolution_parameter = seq.int(0, max(abs(network)), 0.01)). For modularity, searches along resolutions from 0 to 2 in 0.05 increments (resolution_parameter = seq.int(0, 2, 0.05)) by default. Use the argument resolution_parameter to change the search parameters (see examples) "louvain" — See community.consensus for more details. By default, searches along resolutions from 0 to 2 in 0.05 increments (resolution_stron 0 to 2 in 0.05 increments (resolution_parameter to change the search parameter = seq.int(0, 2, 0.05)). Use the argument resolution_parameter to change the search parameter to change the search parameter to change the search parameter = seq.int(0, 2, 0.05)). Use the argument resolution_parameter to change the search parameter to change the search parameter to change the search parameter = seq.int(0, 2, 0.05)).

	• "walktrap" — This algorithm is the default. See cluster_walktrap for more details. By default, searches along 3 to 8 steps (steps = 3:8). Use the argument steps to change the search parameters (see examples)
plot.EGA	Boolean. If TRUE, returns a plot of the network and its estimated dimensions. Defaults to TRUE
verbose	Boolean. Whether messages and (insignificant) warnings should be output. De- faults to FALSE (silent calls). Set to TRUE to see all messages and warnings for every function call
	Additional arguments to be passed on to auto.correlate, network.estimation, community.detection, community.consensus, and EGA.estimate

Value

Returns a list containing:

EGA	EGA results of the best fitting solution
EntropyFit	tefi fit values for each solution
Lowest.EntropyF	it
	The best fitting solution based on ${\tt tefi}$
parameter.space	
	Demander and the second in second second

Parameter values used in search space

```

ega.wmt

EGA Network of wmt2Data

Description

EGA results from ega.wmt <- EGA(wmt2[,7:24]) for the Wiener Matrizen-Test (WMT-2)

Usage

data(ega.wmt)

Format

A list with 8 objects (see Value in EGA)

Examples

data("ega.wmt")

EGAnet-plot

S3 Plot Methods for EGAnet

Description

General usage for plots created by EGAnet's S3 methods. Plots across the EGAnet package leverage GGally's ggnet2 and ggplot2's ggplot.

Most plots allow the full usage of the gg* series functionality and therefore plotting arguments should be referenced through those packages rather than here in EGAnet.

The sections below list the functions and their usage for the S3 plot methods. The plot methods are intended to be generic and without many arguments so that nearly all arguments are passed to ggnet2 and ggplot.

There are some constraints placed on certain plots to keep the EGAnet style throughout the (network) plots in the package, so be aware that if some settings are not changing your plot output, then these settings might be fixed to maintain the EGAnet style

General Usage

```
plot(x, ...)
plot.dynEGA(x, base = 1, id = NULL, ...)
plot.dynEGA.Group(x, base = 1, ...)
plot.dynEGA.Individual(x, base = 1, id = NULL, ...)
plot.hierEGA(
    x, plot.type = c("multilevel", "separate"),
    color.match = FALSE, ...
)
plot.invariance(x, p_type = c("p", "p_BH"), p_value = 0.05, ...)
plot.TEFI.compare(x, base.name, comparison.name, base.color, comparison.color, ...)
```

58

EGAnet-plot

General Arguments

- x EGAnet object with available S3 plot method (see full list below)
- color.palette Character (vector). Either a character (length = 1) from the pre-defined palettes in color_palette_EGA or character (length = total number of communities) using HEX codes (see **Color Palettes** and **Examples** sections)
- layout Character (length = 1). Layouts can be set using gplot.layout and the ending layout name; for example, gplot.layout.circle can be set in these functions using layout = "circle" or mode = "circle" (see Examples)
- base Numeric (length = 1). Plot to be used as the base for the configuration of the networks. Uses the number of the order in which the plots are input. Defaults to 1 or the first plot
- id Numeric index(es) or character name(s). IDs to use when plotting dynEGA level = "individual". Defaults to NULL or 4 IDs drawn at random
- plot.type Character (length = 1). Whether hierEGA networks should plotted in a stacked, "multilevel" fashion or as "separate" plots. Defaults to "multilevel"
- color.match Boolean (length = 1). Whether lower order community colors in the hierEGA plot should be "matched" and used as the border color for the higher order communities. Defaults to FALSE
- p_type Character (length = 1). Type of *p*-value when plotting invariance. Defaults to "p" or uncorrected *p*-value. Set to "p_BH" for the Benjamini-Hochberg corrected *p*-value
- p_value Numeric (length = 1). The *p*-value to use alongside p_type when plotting invariance. Defaults to 0.05
- base.name Character (length = 1). A string to label the base structure in the plot. Defaults to "Base"
- comparison.name Character (length = 1). A string to label the comparison structure in the plot. Defaults to "Comparison"
- base.color Character (length = 1). A string to specifying the color of the base structure in the plot. Hex codes can be used. Defaults to "blue"
- comparison.color Character (length = 1). A string to specifying the color of the comparison structure in the plot. Hex codes can be used. Defaults to "red"
- ... Additional arguments to pass on to ggnet2 and gplot.layout (see Examples)

*EGA Plots

bootEGA, dynEGA, EGA, EGA. estimate, EGA. fit, hierEGA, invariance, riEGA

All Available S3 Plot Methods

boot.ergoInfo, bootEGA, dynEGA, dynEGA.Group, dynEGA.Individual, dynEGA.Population, EGA, EGA.estimate, EGA.fit, hierEGA, infoCluster, invariance, itemStability, riEGA

Color Palettes

color_palette_EGA will implement some color palettes in EGAnet. The main EGAnet style palette is "polychrome". This palette currently has 40 colors but there will likely be a need to expand it further (e.g., hierEGA demands a lot of colors).

The color.palette argument will also accept HEX code colors that are the same length as the number of communities in the plot.

In any network plots, the color.palette argument can be used to select color palettes from color_palette_EGA as well as those in the color scheme of RColorBrewer

For more worked examples than below, see *Plots in {EGAnet}*

Examples

```
# Using different arguments in {GGally}'s `ggnet2`
plot(ega.wmt, node.size = 6, edge.size = 4)
# Using a different layout in {sna}'s `gplot.layout`
plot(ega.wmt, layout = "circle") # 'layout' argument
plot(ega.wmt, mode = "circle") # 'mode' argument
# Using different color palettes with `color_palette_EGA`
## Pre-defined palette
plot(ega.wmt, color.palette = "blue.ridge2")
## University of Virginia colors
plot(ega.wmt, color.palette = c("#232D4B", "#F84C1E"))
## Vanderbilt University colors
## (with additional {GGally} `ggnet2` argument)
plot(
  ega.wmt, color.palette = c("#FFFFFF", "#866D4B"),
  label.color = "#000000"
)
```

EGM

Exploratory Graph Model

Description

Function to fit the Exploratory Graph Model

Usage

```
EGM(
   data,
   EGM.model = c("standard", "EGA"),
   communities = NULL,
   structure = NULL,
   search = FALSE,
   p.in = NULL,
   p.out = NULL,
```

60

```
opt = c("AIC", "BIC", "logLik", "SRMR"),
constrain.structure = TRUE,
constrain.zeros = TRUE,
verbose = TRUE,
...
```

Arguments

data	Matrix or data frame. Should consist only of variables to be used in the analysis. Can be raw data or a correlation matrix
EGM.model	Character vector (length = 1). Sets the procedure to conduct EGM. Available options:
	• "EGA" (default) — Applies EGA to obtain the (sparse) regularized network structure, communities, and memberships
	 "standard" — Applies the standard EGM model which estimates commu- nities based on the non-regularized empirical partial correlation matrix and sparsity is set using p.in and p.out
communities	Numeric vector (length = 1). Number of communities to use for the "standard" type of EGM. Defaults to NULL. Providing no input will use the communities and memberships output from the Walktrap algorithm (cluster_walktrap) based on the empirical non-regularized partial correlation matrix
structure	Numeric or character vector (length = ncol(data)). Can be theoretical factors or the structure detected by EGA. Defaults to NULL
search	Boolean (length = 1). Whether a search over parameters should be conducted. Defaults to FALSE. Set to TRUE to select a model over a variety of parameters that optimizes the opt objective
p.in	Numeric vector (length = 1). Probability that a node is randomly linked to other nodes in the same community. Within community edges are set to zero based on $quantile(x, prob = 1 - p.in)$ ensuring the lowest edge values are set to zero (i.e., most probable to <i>not</i> be randomly connected). Only used for EGM.type = "standard". Defaults to NULL but must be set
p.out	Numeric vector (length = 1). Probability that a node is randomly linked to other nodes <i>not</i> in the same community. Between community edges are set to zero based on quantile(x, prob = $1 - p$.out) ensuring the lowest edge values are set to zero (i.e., most probable to <i>not</i> be randomly connected). Only used for EGM.type = "standard" and search = FALSE. Defaults to NULL but must be set
opt	<pre>Character vector (length = 1). Fit index used to select from when searching over models (only applies to search = TRUE). Available options include: "AIC" "BIC" "logLik" "SRMR"</pre>

Defaults to "SRMR"

constrain.structure

Boolean (length = 1). Whether memberships of the communities should be added as a constraint when optimizing the network loadings. Defaults to TRUE which ensures assigned loadings are guaranteed to never be smaller than any cross-loadings. Set to FALSE to freely estimate each loading similar to exploratory factor analysis

constrain.zeros

	Boolean (length = 1). Whether zeros in the estimated network loading matrix should be retained when optimizing the network loadings. Defaults to TRUE which ensures that zero networks loadings are retained. Set to FALSE to freely estimate each loading similar to exploratory factor analysis
verbose	Boolean (length = 1). Should progress be displayed? Defaults to TRUE. Set to FALSE to not display progress
	Additional arguments to be passed on to auto.correlate, network.estimation community.detection, community.consensus, community.unidimensional, EGA, and net.loads

Examples

```
# Get depression data
data <- depression[,24:44]</pre>
# Estimate EGM (using EGA)
egm_ega <- EGM(data)
# Estimate EGM (using EGA) specifying communities
egm_ega_communities <- EGM(data, communities = 3)</pre>
# Estimate EGM (using EGA) specifying structure
egm_ega_structure <- EGM(</pre>
 data, structure = c(
   1, 1, 1, 2, 1, 1, 1,
   1, 1, 1, 3, 2, 2, 2,
    2, 3, 3, 3, 3, 3, 2
 )
)
# Estimate EGM (using standard)
egm_standard <- EGM(</pre>
 data, EGM.model = "standard",
 communities = 3, # specify number of communities
 p.in = 0.95, # probability of edges *in* each community
 p.out = 0.80 # probability of edges *between* each community
)
## Not run:
# Estimate EGM (using EGA search)
```

EGM.compare

```
egm_ega_search <- EGM(
  data, EGM.model = "EGA", search = TRUE
)
# Estimate EGM (using EGA search and AIC criterion)
egm_ega_search_AIC <- EGM(
  data, EGM.model = "EGA", search = TRUE, opt = "AIC"
)
# Estimate EGM (using search)
egm_search <- EGM(
  data, EGM.model = "standard", search = TRUE,
  communities = 3, # need communities or structure
  p.in = 0.95 # only need 'p.in'
)
## End(Not run)
```

EGM.compare

Compare EGM with EFA

Description

Estimates an EGM based on EGA and uses the number of communities as the number of dimensions in exploratory factor analysis (EFA) using fa

Usage

```
EGM.compare(
   data,
   constrain.structure = FALSE,
   constrain.zeros = FALSE,
   rotation = "geominQ",
   ...
)
```

Arguments data

```
Matrix or data frame. Should consist only of variables to be used in the analysis.
Can be raw data or a correlation matrix
```

constrain.structure

Boolean (length = 1). Whether memberships of the communities should be added as a constraint when optimizing the network loadings. Defaults to TRUE which ensures assigned loadings are guaranteed to never be smaller than any cross-loadings. Set to FALSE to freely estimate each loading similar to exploratory factor analysis

#' Note: This default differs from EGM. Constraining loadings puts EGM at a deficit relative to EFA and therefore biases the comparability between the methods. It's best to leave the default of unconstrained when using this function.

constrain.zeros	
	Boolean (length = 1). Whether zeros in the estimated network loading matrix should be retained when optimizing the network loadings. Defaults to TRUE which ensures that zero networks loadings are retained. Set to FALSE to freely estimate each loading similar to exploratory factor analysis
	<i>Note: This default differs from</i> EGM. <i>Constraining zeros puts</i> EGM at a deficit relative to EFA and therefore biases the comparability between the methods. It's best to leave the default of unconstrained when using this function.
rotation	Character. A rotation to use to obtain a simpler structure for EFA. For a list of rotations, see rotations for options. Defaults to "geominQ"
	Additional arguments to be passed on to auto.correlate, network.estimation, community.detection, community.consensus, community.unidimensional, EGA, EGM, net.loads, and fa

Hudson F. Golino <hfg9s at virginia.edu> and Alexander P. Christensen <alexpaulchristensen@gmail.com>

Examples

```
# Get depression data
data <- depression[,24:44]
# Compare EGM (using EGA) with EFA
## Not run:
results <- EGM.compare(data)
# Print summary
summary(results)
## End(Not run)</pre>
```

Embed

Time-delay Embedding

Description

Reorganizes a single observed time series into an embedded matrix. The embedded matrix is constructed with replicates of an individual time series that are offset from each other in time. The function requires two parameters, one that specifies the number of observations to be used (i.e., the number of embedded dimensions) and the other that specifies the number of observations to offset successive embeddings

Usage

Embed(x, E, tau)

entropyFit

Arguments

x	Numeric vector. An observed time series to be reorganized into a time-delayed embedded matrix.
E	Numeric (length = 1). Number of embedded dimensions or the number of observations to be used. E = 5, for example, will generate a matrix with five columns corresponding to five consecutive observations across each row of the embedded matrix
tau	Numeric (length = 1). Number of observations to offset successive embeddings. A tau of one uses adjacent observations. Default is tau = 1

Value

Returns a numeric matrix

time_series <- 49:56</pre>

Time series embedding
Embed(time_series, E = 5, tau = 1)

entropyFit Entropy Fit Index

Description

Computes the fit of a dimensionality structure using empirical entropy. Lower values suggest better fit of a structure to the data.

Usage

entropyFit(data, structure)

Arguments

data	Matrix or data frame. Contains variables to be used in the analysis
structure	Numeric or character vector (length = ncol(data)). A vector representing the
	structure (numbers or labels for each item). Can be theoretical factors or the
	structure detected by EGA

Value

Returns a list containing:

Total.Correlati	on
	The total correlation of the dataset
Total.Correlati	on.MM
	Miller-Madow correction for the total correlation of the dataset
Entropy.Fit	The Entropy Fit Index
Entropy.Fit.MM	Miller-Madow correction for the Entropy Fit Index
Average.Entropy	
	The evenese entropy of the detect

The average entropy of the dataset

Author(s)

Entropy fit indices: New fit measures for assessing the structure and dimensionality of multiple latent variables. *Multivariate Behavioral Research*.

Examples

```
# Load data
wmt <- wmt2[,7:24]
## Not run:
# Estimate EGA model
ega.wmt <- EGA(data = wmt)
## End(Not run)
# Compute entropy indices</pre>
```

entropyFit(data = wmt, structure = ega.wmt\$wc)

ergoInfo

Description

Computes the Ergodicity Information Index

Usage

```
ergoInfo(
  dynEGA.object,
  use = c("edge.list", "unweighted", "weighted"),
  shuffles = 5000
)
```

Arguments

dynEGA.object	A dynEGA.ind.pop object
use	Character (length = 1). A string indicating what network element will be used to compute the algorithm complexity, the list of edges or the weights of the network. Defaults to use = "unweighted". Current options are:
	 "edge.list" — Calculates the algorithm complexity using the list of edges "unweighted" — Calculates the algorithm complexity using the binary weights of the encoded prime transformed network. 0 = edge absent and 1 = edge present
	• "weighted" — Calculates the algorithm complexity using the weights of encoded prime-weight transformed network
shuffles	Numeric. Number of shuffles used to compute the Kolmogorov complexity. Defaults to 5000

Value

Returns a list containing:

PrimeWeight	The prime-weight encoding of the individual networks	
PrimeWeight.pop		
	The prime-weight encoding of the population network	
Kcomp	The Kolmogorov complexity of the prime-weight encoded individual networks	
Kcomp.pop	The Kolmogorov complexity of the prime-weight encoded population network	
complexity	The complexity metric proposed by Santora and Nicosia (2020)	
EII	The Ergodicity Information Index

Examples

```
# Obtain data
sim.dynEGA <- sim.dynEGA # bypasses CRAN checks
## Not run:
# Dynamic EGA individual and population structure
dyn.ega1 <- dynEGA.ind.pop(
   data = sim.dynEGA[,-26], n.embed = 5, tau = 1,
   delta = 1, id = 25, use.derivatives = 1,
   ncores = 2, corr = "pearson"
)
# Compute empirical ergodicity information index
eii <- ergoInfo(dyn.ega1)
## End(Not run)
```

frobenius

Frobenius Norm (Similarity)

Description

Computes the Frobenius Norm (Ulitzsch et al., 2023)

Usage

```
frobenius(network1, network2)
```

Arguments

network1	Matrix or data frame. Ne	etwork to be compared
network2	Matrix or data frame. Se	cond network to be compared

Value

Returns Frobenius Norm

Author(s)

Hudson Golino <hfg9s at virginia.edu> & Alexander P. Christensen <alexander.christensen at Vanderbilt.Edu>

genTEFI

Simulation Study

Ulitzsch, E., Khanna, S., Rhemtulla, M., & Domingue, B. W. (2023). A graph theory based similarity metric enables comparison of subpopulation psychometric networks *Psychological Methods*.

Examples

```
# Obtain wmt2 data
wmt <- wmt2[,7:24]</pre>
# Set seed (for reproducibility)
set.seed(1234)
# Split data
split1 <- sample(</pre>
  1:nrow(wmt), floor(nrow(wmt) / 2)
)
split2 <- setdiff(1:nrow(wmt), split1)</pre>
# Obtain split data
data1 <- wmt[split1,]</pre>
data2 <- wmt[split2,]</pre>
# Perform EBICglasso
glas1 <- EBICglasso.ggraph(data1)</pre>
glas2 <- EBICglasso.qgraph(data2)</pre>
# Frobenius norm
frobenius(glas1, glas2)
# 0.7070395
```

genTEFI

Generalized Total Entropy Fit Index using Von Neumman's entropy (Quantum Information Theory) for correlation matrices

Description

Computes the fit (Generalized TEFI) of a hierarchical or correlated bifactor dimensionality structure (or hierEGA objects) using Von Neumman's entropy when the input is a correlation matrix. Lower values suggest better fit of a structure to the data

Usage

genTEFI(data, structure = NULL, verbose = TRUE)

Arguments

data	Matrix, data frame, or hierEGA object. Can be raw data or correlation matrix
structure	For high-order and correlated bifactor structures, structure should be a list containing:
	• lower_order — A vector (length = ncol(data)) representing the first- order structure (numbers or labels for each item in each first-order factor or community)
	 higher_order — A vector (length = ncol(data) or number of lower_order communities)representing the second-order structure (numbers or labels for each item in each second-order factor or community)
verbose	Boolean (length = 1). Whether messages and (insignificant) warnings should be output. Defaults to TRUE to see all messages and warnings for every function call. Set to FALSE to ignore messages and warnings

Value

Returns a three-column data frame of the Generalized Total Entropy Fit Index using Von Neumman's entropy (VN.Entropy.Fit) (first column), as well as Lower.Order.VN - TEFI for the firstorder factors (second column), and Higher.Order.VN, the equivalent for the second-order factors.

Author(s)

Hudson Golino <hfg9s at virginia.edu> and Alexander P. Christensen <alexpaulchristensen@gmail.com>

Examples

```
# Example using network scores
opt.hier <- hierEGA(
   data = optimism, scores = "network",
   plot.EGA = FALSE # No plot for CRAN checks
)
# Compute the Generalized Total Entropy Fit Index
genTEFI(opt.hier)</pre>
```

glla

```
Generalized Local Linear Approximation
```

Description

Estimates the derivatives of a time series using generalized local linear approximation (GLLA). GLLA is a filtering method for estimating derivatives from data that uses time delay embedding and a variant of Savitzky-Golay filtering to accomplish the task.

Usage

glla(x, n.embed, tau, delta, order)

Arguments

х	Numeric vector. An observed time series
n.embed	Numeric (length = 1). Number of embedded dimensions (the number of observations to be used in the Embed function)
tau	Numeric (length = 1). Number of observations to offset successive embeddings in the Embed function. A tau of one uses adjacent observations. Default is 1
delta	Numeric (length = 1). The time between successive observations in the time series. Default is 1
order	Numeric (length = 1). The maximum order of the derivative to be estimated. For example, "order = 2" will return a matrix with three columns with the estimates of the observed scores and the first and second derivative for each row of the embedded matrix (i.e. the reorganization of the time series implemented via the Embed function)

Value

Returns a matrix containing *n* columns in which *n* is one plus the maximum order of the derivatives to be estimated via generalized local linear approximation

Author(s)

Hudson Golino <hfg9s at virginia.edu>

References

Filtering procedure

Savitzky, A., & Golay, M. J. (1964). Smoothing and differentiation of data by simplified least squares procedures. *Analytical Chemistry*, *36*(8), 1627-1639.

Examples

```
# A time series with 8 time points
tseries <- 49:56
deriv.tseries <- glla(tseries, n.embed = 4, tau = 1, delta = 1, order = 2)</pre>
```

hierEGA

Description

Estimates EGA using the lower-order solution of the Louvain algorithm (cluster_louvain)to identify the lower-order dimensions and then uses factor or network loadings to estimate factor or network scores, which are used to estimate the higher-order dimensions (for more details, see Jiménez et al., 2023)

Usage

```
hierEGA(
  data,
  loading.method = c("original", "revised"),
  rotation = NULL,
  scores = c("factor", "network"),
  loading.structure = c("simple", "full"),
  impute = c("mean", "median", "none"),
  corr = c("auto", "cor_auto", "pearson", "spearman"),
  na.data = c("pairwise", "listwise"),
 model = c("BGGM", "glasso", "TMFG"),
  lower.algorithm = "louvain",
  higher.algorithm = c("leiden", "louvain", "walktrap"),
  uni.method = c("expand", "LE", "louvain"),
  plot.EGA = TRUE,
  verbose = FALSE,
  . . .
```

Arguments

)

data	Matrix or data frame. Should consist only of variables to be used in the analysis (does not accept correlation matrices)
loading.method	Character (length = 1). Sets network loading calculation based on implementa- tion described in "original" (Christensen & Golino, 2021) or the "revised" (Christensen et al., 2024) implementation. Defaults to "revised"
rotation	Character. A rotation to use to obtain a simpler structure. For a list of rota- tions, see rotations for options. Defaults to NULL or no rotation. By setting a rotation, scores estimation will be based on the rotated loadings rather than unrotated loadings
scores	Character (length = 1). How should scores for the higher-order structure be esti- mated? Defaults to "network" for network scores computed using the net.scores function. Set to "factor" for factor scores computed using fa. Factors scores will be based on EFA (as in Jiménez et al., 2023)
	Factor scores use the number of communities from EGA. Estimated factor load- ings may not align with these communities. The plots using factor scores will have higher order factors that may not completely map on to the lower order communities. Look at \$hierarchical\$higher_order\$lower_loadings to de- termine the composition of the lower order factors.
--------------	---
loading.stru	cture
	Character (length = 1). Whether simple structure or the saturated loading matrix should be used when computing scores (scores = "network" only). Defaults to "simple"
	"simple" structure more closely mirrors traditional hierarchical factor analytic methods such as CFA; "full" structure more closely mirrors EFA methods
	Simple structure is the more conservative (established) approach and is therefore the default. Treat "full" as experimental as proper vetting and validation has not been established
impute	Character (length = 1). If there are any missing data, then imputation can be implemented. Available options:
	• "none" — Default. No imputation is performed
	• "mean" — The mean value of each variable is used to replace missing data for that variable
	• "median" — The median value of each variable is used to replace missing data for that variable
corr	Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:
	• "auto" — Automatically computes appropriate correlations for the data us- ing Pearson's for continuous, polychoric for ordinal, tetrachoric for binary, and polyserial/biserial for ordinal/binary with continuous. To change the number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details)
	• "cor_auto" — Uses cor_auto to compute correlations. Arguments can be passed along to the function
	• "pearson" — Pearson's correlation is computed for all variables regardless of categories
	• "spearman" — Spearman's rank-order correlation is computed for all vari- ables regardless of categories
	For other similarity measures, compute them first and input them into data with the sample size (n)
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
	• "pairwise" — Computes correlation for all available cases between two variables
	• "listwise" — Computes correlation for all complete cases in the dataset
model	Character (length = 1). Defaults to "glasso". Available options:
	• "BGGM" — Computes the Bayesian Gaussian Graphical Model. Set argument ordinal.categories to determine levels allowed for a variable to be considered ordinal. See ?BGGM::estimate for more details

- "glasso" Computes the GLASSO with EBIC model selection. See EBICglasso.ggraph for more details
- "TMFG" Computes the TMFG method. See TMFG for more details

lower.algorithm

Character or cluster_* function (length = 1). Defaults to the lower order "louvain" with most common consensus clustering (1000 iterations; see community.consensus for more details)

Louvain with consensus clustering is *strongly* recommended. Using any other algorithm is considered *experimental* as they have not been designed to capture lower order communities

higher.algorithm

Character or cluster_* function (length = 1). Defaults to "louvain". Three options are listed below but all are available (see community.detection for other options):

- "leiden" See cluster_leiden for more details
- "louvain" By default, "louvain" will implement the higher-order (order = "higher") Louvain algorithm using the consensus clustering method (see community.consensus for more information). This function will implement consensus.method = "most_common" and consensus.iter = 1000 unless specified otherwise
- "walktrap" See cluster_walktrap for more details

Using algorithm will set only higher.algorithm and lower.algorithm will default to Louvain with most common consensus clustering (1000 iterations)

uni.method Character (length = 1). What unidimensionality method should be used? Defaults to "louvain". Available options:

- "expand" Expands the correlation matrix with four variables correlated 0.50. If number of dimension returns 2 or less in check, then the data are unidimensional; otherwise, regular EGA with no matrix expansion is used. This method was used in the Golino et al.'s (2020) *Psychological Methods* simulation
- "LE" Applies the Leading Eigenvector algorithm (cluster_leading_eigen) on the empirical correlation matrix. If the number of dimensions is 1, then the Leading Eigenvector solution is used; otherwise, regular EGA is used. This method was used in the Christensen et al.'s (2023) *Behavior Research Methods* simulation
- "louvain" Applies the Louvain algorithm (cluster_louvain) on the empirical correlation matrix. If the number of dimensions is 1, then the Louvain solution is used; otherwise, regular EGA is used. This method was validated Christensen's (2022) *PsyArXiv* simulation. Consensus clustering can be used by specifying either "consensus.method" or "consensus.iter"
- plot.EGA Boolean. If TRUE, returns a plot of the network and its estimated dimensions. Defaults to TRUE

verbose Boolean (length = 1). Whether messages and (insignificant) warnings should be output. Defaults to FALSE (silent calls). Set to TRUE to see all messages and warnings for every function call

... Additional arguments to be passed on to auto.correlate, network.estimation, community.detection, community.consensus, EGA, and rotations

hierEGA

Value

Returns a list of lists containing:

lower_order	EGA results for the lower order structure
higher_order	EGA results for the higher order structure
parameters	A list containing lower_loadings and lower_scores that were used to esti- mate scores and the higher order EGA results, respectively
dim.variables	A data frame with variable names and their lower and higher order assignments
TEFI	Generalized TEFI using tefi
plot.hierEGA	Plot output if plot.EGA = TRUE

igraph2matrix Convert network to matrix

Description

Converts network to matrix

Usage

```
igraph2matrix(igraph_network, diagonal = 0)
```

Arguments

```
igraph_network network object
diagonal Numeric (length = 1). Value to be placed on the diagonal of network. Defaults
to 0
```

Value

Returns a network in the format

Author(s)

Hudson Golino <hfg9s at virginia.edu> & Alexander P. Christensen <alexander.christensen at Vanderbilt.Edu>

Examples

```
# Convert network to {igraph}
igraph_network <- convert2igraph(ega.wmt$network)
# Convert network back to matrix</pre>
```

igraph2matrix(igraph_network)

infoCluster

Description

Performs hierarchical clustering using Jensen-Shannon distance followed by the Louvain algorithm with consensus clustering. The method iteratively identifies smaller and smaller clusters until there is no change in the clusters identified

Usage

```
infoCluster(dynEGA.object, plot.cluster = TRUE, ...)
```

Arguments

dynEGA.object	A dynEGA or a dynEGA.ind.pop object that is used to match the arguments of the EII object
plot.cluster	Boolean (length = 1). Should plot of optimal and hierarchical clusters be output? Defaults to TRUE. Set to FALSE to not plot
	Additional arguments to be passed on to jsd

Value

Returns a list containing:

clusters	A vector corresponding to cluster each participant belongs to
clusterTree	The dendogram from hclust the hierarhical clustering
clusterPlot	Plot output from results
JSD	Jensen-Shannon Distance

Author(s)

Hudson Golino <hfg9s at virginia.edu> & Alexander P. Christensen <alexander.christensen at Vanderbilt.Edu>

information

Information Theory Metrics

Description

A general function to compute several different information theory metrics

Usage

```
information(
   data,
   base = 2.718282,
   bins = floor(sqrt(nrow(data)/5)),
   statistic = c("entropy", "joint.entropy", "conditional.entropy", "total.correlation",
      "dual.total.correlation", "o.information")
)
```

Arguments

data	Matrix or data frame. Should consist only of variables to be used in the analysis
base	Numeric (length = 1). Base of logarithm to use for entropy. Common options include:
	 2 — bits 2.718282 — nats 10 — bans
	Defaults to exp(1) or 2.718282
bins	Numeric (length = 1). Number of bins if data are not discrete. Defaults to floor(sqrt(nrow(data) / 5))
statistic	Character. Information theory statistics to compute. Available options:
	 "entropy" — Shannon's entropy (Shannon, 1948) for each variable in data. Values range from 0 to log(k) where k is the number of categories for the variable
	• "joint.entropy" — shared uncertainty over all variables in data. Values range from the maximum of the individual entropies to the sum of individual entropies

information

- "conditional.entropy" uncertainty remaining after considering all other variables in data. Values range from 0 to the individual entropy of the conditioned variable
- "total.correlation" generalization of mutual information to more than two variables (Watanabe, 1960). Quantifies the redundancy of information in data. Values range from 0 to the sum of individual entropies minus the maximum of the individual entropies
- "dual.total.correlation" "shared randomness" or total uncertainty remaining in the data (Han, 1978). Values range from 0 to joint entropy
- "o.information" quantifies the extent to which the data is represented by lower-order (> 0; redundancy) or higher-order (< 0; synergy) constraint (Crutchfield, 1994)

By default, all statistics are computed

Value

Returns list containing only requested statistic

intelligenceBattery Intelligence Data

Description

A response matrix (n = 1152) of the International Cognitive Ability Resource (ICAR) intelligence battery developed by Condon and Revelle (2016).

Usage

```
data(intelligenceBattery)
```

Format

A 1185x125 response matrix

Examples

data("intelligenceBattery")

invariance

Measurement Invariance of EGA Structure

Description

Estimates configural invariance using bootEGA on all data (across groups) first. After configural variance is established, then metric invariance is tested using the community structure that established configural invariance (see **Details** for more information on this process)

invariance

Usage

```
invariance(
 data,
 groups,
 structure = NULL,
 iter = 500,
 configural.threshold = 0.7,
 configural.type = c("parametric", "resampling"),
  corr = c("auto", "cor_auto", "pearson", "spearman"),
 na.data = c("pairwise", "listwise"),
 model = c("BGGM", "glasso", "TMFG"),
 algorithm = c("leiden", "louvain", "walktrap"),
 uni.method = c("expand", "LE", "louvain"),
 ncores,
  seed = NULL,
 verbose = TRUE,
  . . .
```

Arguments

)

data	Matrix or data frame. Should consist only of variables to be used in the analysis
groups	Numeric or character vector (length = nrow(data)). Group membership corresponding to each case in data
structure	Numeric or character vector (length = $ncol(data)$). A vector representing the structure (numbers or labels for each item). Can be theoretical factors or the structure detected by EGA. If supplied, then configural invariance check is skipped (i.e., configural invariance is assumed based on the given structure)
iter	Numeric (length = 1). Number of iterations to perform for the permutation. Defaults to 500 (recommended)
configural.thre	eshold
	Numeric (length = 1). Value to use a threshold in itemStability to determine which items should be removed during configural invariance (see Details for more information). Defaults to 0.70 (recommended)
configural.type	
	Character (length = 1). Type of bootstrap to use for configural invariance in bootEGA. Defaults to "parametric"
corr	Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:
	 "auto" — Automatically computes appropriate correlations for the data using Pearson's for continuous, polychoric for ordinal, tetrachoric for binary, and polyserial/biserial for ordinal/binary with continuous. To change the number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details) "cor_auto" — Uses cor_auto to compute correlations. Arguments can be passed along to the function

	 "pearson" — Pearson's correlation is computed for all variables regardless of categories
	 "spearman" — Spearman's rank-order correlation is computed for all vari- ables regardless of categories
	For other similarity measures, compute them first and input them into data with the sample size (n)
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
	 "pairwise" — Computes correlation for all available cases between two variables
	• "listwise" — Computes correlation for all complete cases in the dataset
model	Character (length = 1). Defaults to "glasso". Available options:
	 "BGGM" — Computes the Bayesian Gaussian Graphical Model. Set argument ordinal.categories to determine levels allowed for a variable to be considered ordinal. See ?BGGM::estimate for more details "glasso" — Computes the GLASSO with EBIC model selection. See EBICglasso.qgraph for more details
	• "TMFG" — Computes the TMFG method. See TMFG for more details
algorithm	Character or cluster_* function (length = 1). Defaults to "walktrap". Three options are listed below but all are available (see community.detection for other options):
	 "leiden" — See cluster_leiden for more details
	 "louvain" — By default, "louvain" will implement the Louvain algorithm using the consensus clustering method (see community.consensus for more information). This function will implement consensus.method = "most_common" and consensus.iter = 1000 unless specified otherwise
	 "walktrap" — See cluster_walktrap for more details
uni.method	Character (length = 1). What unidimensionality method should be used? Defaults to "louvain". Available options:
	• "expand" — Expands the correlation matrix with four variables correlated 0.50. If number of dimension returns 2 or less in check, then the data are unidimensional; otherwise, regular EGA with no matrix expansion is used. This method was used in the Golino et al.'s (2020) <i>Psychological Methods</i> simulation
	• "LE" — Applies the Leading Eigenvector algorithm (cluster_leading_eigen) on the empirical correlation matrix. If the number of dimensions is 1, then the Leading Eigenvector solution is used; otherwise, regular EGA is used. This method was used in the Christensen et al.'s (2023) <i>Behavior Research</i> <i>Methods</i> simulation
	 "louvain" — Applies the Louvain algorithm (cluster_louvain) on the empirical correlation matrix. If the number of dimensions is 1, then the Louvain solution is used; otherwise, regular EGA is used. This method was validated Christensen's (2022) <i>PsyArXiv</i> simulation. Consensus clustering can be used by specifying either "consensus.method" or "consensus.iter"

invariance

ncores	Numeric (length = 1). Number of cores to use in computing results. Defaults to ceiling(parallel::detectCores() / 2) or half of your computer's process- ing power. Set to 1 to not use parallel computing
	If you're unsure how many cores your computer has, then type: parallel::detectCores()
seed	Numeric (length = 1). Defaults to NULL or random results. Set for reproducible results. See Reproducibility and PRNG for more details on random number generation in
verbose	Boolean (length = 1). Should progress be displayed? Defaults to TRUE. Set to FALSE to not display progress
	Additional arguments that can be passed on to auto.correlate, network.estimation, community.detection, community.consensus, EGA, bootEGA, and net.loads

Details

In traditional psychometrics, measurement invariance is performed in sequential testing from more flexible (more free parameters) to more rigid (fewer free parameters) structures. Measurement invariance in network psychometrics is no different.

Configural Invariance

To establish configural invariance, the data are collapsed across groups and a common sample structure is identified used bootEGA and itemStability. If some variables have a replication less than 0.70 in their assigned dimension, then they are considered unstable and therefore not invariant. These variables are removed and this process is repeated until all items are considered stable (replication values greater than 0.70) or there are no variables left. If configural invariance cannot be established, then the last run of results are returned and metric invariance is not tested (because configural invariance is not met). Importantly, if any variables *are* removed, then configural invariance is not met for the original structure. Any removal would suggest only partial configural invariance is met.

Metric Invariance

The variables that remain after configural invariance are submitted to metric invariance. First, each group estimates a network and then network loadings (net.loads) are computed using the assigned community memberships (determined during configural invariance). Then, the difference between the assigned loadings of the groups is computed. This difference represents the empirical values. Second, the group memberships are permutated and networks are estimated based on the these permutated groups for iter times. Then, network loadings are computed and the difference between the assigned loadings of the group is computed, resulting in a null distribution. The empirical difference is then compared against the null distribution using a two-tailed *p*-value based on the number of null distribution differences that are greater and less than the empirical differences for each variable. Both uncorrected and false discovery rate corrected *p*-values are returned in the results. Uncorrected *p*-values are flagged for significance along with the direction of group differences.

Three or More Groups

When there are 3 or more groups, the function performs metric invariance testing by comparing all possible pairs of groups. Specifically:

• *Pairwise Comparisons*: The function generates all possible unique group pairings and computes the differences in network loadings for each pair. The same community structure, derived from configural invariance or provided by the user, is used for all groups.

- *Permutation Testing*: For each group pair, permutation tests are conducted to assess the statistical significance of the observed differences in loadings. *p*-values are calculated based on the proportion of permuted differences that are greater than or equal to the observed difference.
- *Result Compilation*: The function compiles the results for each pair including both uncorrected (p) and FDR-corrected (Benjamini-Hochberg; p_BH) *p*-values, and the direction of differences. It returns a summary of the findings for all pairwise comparisons.

This approach allows for a detailed examination of metric invariance across multiple groups, ensuring that all potential differences are thoroughly assessed while maintaining the ability to identify specific group differences.

For more details, see Jamison, Golino, and Christensen (2023)

Value

Returns a list containing:

configural.results

-	bootEGA results from the final run that produced configural invariance. This output will be output on the final run of unsuccessful configural invariance runs
memberships	Original memberships provided in structure or from EGA if structure = NULL
EGA	Original EGA results for the full sample
groups	A list containing:
	 EGA — EGA results for each group loadings — Network loadings (net.loads) for each group loadingsDifference — Difference between the dominant loadings of each group
permutation	A list containing:
	 groups — Permutated groups acorss iterations loadings — Network loadings (net.loads) for each group for each permutation loadingsDifference — Difference between the dominant loadings of each group for each permutation
results	Data frame of the results (which are printed)

# Groups
groups <- rep(1:2, each = nrow(wmt) / 2)
## Not run:
# Measurement invariance
results <- invariance(wmt, groups, ncores = 2)
# Plot with uncorrected alpha = 0.05
plot(results, p_type = "p", p_value = 0.05)
# Plot with BH-corrected alpha = 0.10
plot(results, p_type = "p_BH", p_value = 0.10)
## End(Not run)</pre>
```

itemDiagnostics Diagnostics Analysis for Low Stability Items

Description

Computes the between- and within-community strength of each variable for each community

Usage

```
itemDiagnostics(data, ...)
```

Arguments

data	Matrix or data frame. Should consist only of variables to be used in the analysis
• • •	Additional arguments to pass on to bootEGA, net.loads, and UVA

Value

Returns a list containing:

diagnostics	A data frame containing the diagnostics of low item stabilities (see itemStability)
boot	Output from bootEGA
uva	Output from UVA
minor	A list containing suggested items to keep, remove, and a matrix for probable minor dimensions (minor.matrix)

loadings	Output from net.loads
suggested	Variables that are suggested to be retained to increase item stability

Author(s)

Alexander P. Christensen <a lexpaulchristensen@gmail.com>, Hudson Golino <hfg9s at virginia.edu>, and Luis Eduardo Garrido <garrido.luiseduardo@gmail.com>

Examples

```
# Load data
wmt <- wmt2[,7:24]
## Not run:
# Obtain diagnostics
diagnostics <- itemDiagnostics(wmt, ncores = 2)
## End(Not run)</pre>
```

itemStability Item Stability Statistics from bootEGA

Description

Based on the bootEGA results, this function computes and plots the number of times an variable is estimated in the same dimension as originally estimated by an empirical EGA structure or a theoretical/input structure. The output also contains each variable's replication frequency (i.e., proportion of bootstraps that a variable appeared in each dimension

Usage

```
itemStability(bootega.obj, IS.plot = TRUE, structure = NULL, ...)
```

Arguments

bootega.obj	A bootEGA object
IS.plot	Boolean (length = 1). Should the plot be produced for item.replication? Defaults to TRUE
structure	Numeric (length = number of variables). A theoretical or pre-defined structure. Defaults to NULL or the empirical EGA result in the bootega.obj
	Deprecated arguments from previous versions of itemStability

itemStability

Value

Returns a list containing:

membership	A list containing:
	• empirical — A vector of the empirical memberships from the empirical EGA result
	• bootstrap — A matrix of the homogenized memberships from the repli- cate samples in the bootEGA results
	• structure — A vector of the structure used in the analysis. If structure = NULL, then this output will be the same as empirical
item.stability	A list containing:
	• empirical.dimensions — A vector of the proportion of times each item replicated within the structure defined by structure
	• all.dimensions — A matrix of the proportion of times each item repli- cated in each of the structure defined dimensions
plot	Plot output if IS.plot = TRUE

jsd

Jensen-Shannon Distance

Description

Computes the Jensen-Shannon Distance between two networks

Usage

```
jsd(network1, network2, method = c("kld", "spectral"), signed = TRUE)
```

Arguments

network1	Matrix or data frame. Network to be compared
network2	Matrix or data frame. Second network to be compared
method	Character (length = 1). Method to compute Jensen-Shannon Distance. Defaults to "spectral". Available options:
	 "kld" — Uses Kullback-Leibler Divergence "spectral" — Uses eigenvalues of combinatorial Laplacian matrix to compute Von Neumann entropy
signed	Boolean. (length = 1). Should networks be remain signed? Defaults to TRUE

Value

Returns Jensen-Shannon Distance

LCT

Loadings Comparison Test

Description

An algorithm to identify whether data were generated from a factor or network model using factor and network loadings. The algorithm uses heuristics based on theory and simulation. These heuristics were then submitted to several deep learning neural networks with 240,000 samples per model with varying parameters.

Usage

```
LCT(
   data,
   n = NULL,
   corr = c("auto", "cor_auto", "pearson", "spearman"),
   na.data = c("pairwise", "listwise"),
   model = c("BGGM", "glasso", "TMFG"),
   algorithm = c("leiden", "louvain", "walktrap"),
   uni.method = c("expand", "LE", "louvain"),
   iter = 100,
   seed = NULL,
   verbose = TRUE,
   ...
)
```

Arguments

data	Matrix or data frame. Should consist only of variables to be used in the analysis. Can be raw data or a correlation matrix
n	Numeric (length = 1). Sample size if data provided is a correlation matrix
corr	Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:
	• "auto" — Automatically computes appropriate correlations for the data us- ing Pearson's for continuous, polychoric for ordinal, tetrachoric for binary, and polyserial/biserial for ordinal/binary with continuous. To change the number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details)

• "cor_auto" — Uses cor_auto to compute correlations. Arguments can be passed along to the function

	 "pearson" — Pearson's correlation is computed for all variables regardless of categories
	 "spearman" — Spearman's rank-order correlation is computed for all variables regardless of categories
	For other similarity measures, compute them first and input them into data with the sample size (n)
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
	 "pairwise" — Computes correlation for all available cases between two variables
	• "listwise" — Computes correlation for all complete cases in the dataset
model	Character (length = 1). Defaults to "glasso". Available options:
	 "BGGM" — Computes the Bayesian Gaussian Graphical Model. Set argument ordinal.categories to determine levels allowed for a variable to be considered ordinal. See ?BGGM::estimate for more details
	• "glasso" — Computes the GLASSO with EBIC model selection. See EBICglasso.qgraph for more details
	• "IMFG" — Computes the IMFG method. See IMFG for more details
algorithm	Character or igraph cluster_* function (length = 1). Defaults to "walktrap". Three options are listed below but all are available (see community.detection for other options):
	 "leiden" — See cluster_leiden for more details
	 "louvain" — By default, "louvain" will implement the Louvain algorithm using the consensus clustering method (see community.consensus for more information). This function will implement consensus.method = "most_common" and consensus.iter = 1000 unless specified otherwise "walktrap" — See cluster_walktrap for more details
uni.method	Character (length = 1). What unidimensionality method should be used? De- faults to "louvain". Available options:
	• "expand" — Expands the correlation matrix with four variables correlated 0.50. If number of dimension returns 2 or less in check, then the data are unidimensional; otherwise, regular EGA with no matrix expansion is used. This method was used in the Golino et al.'s (2020) <i>Psychological Methods</i> simulation
	 "LE" — Applies the Leading Eigenvector algorithm (cluster_leading_eigen) on the empirical correlation matrix. If the number of dimensions is 1, then the Leading Eigenvector solution is used; otherwise, regular EGA is used. This method was used in the Christensen et al.'s (2023) <i>Behavior Research</i> <i>Methods</i> simulation
	 "louvain" — Applies the Louvain algorithm (cluster_louvain) on the empirical correlation matrix. If the number of dimensions is 1, then the Louvain solution is used; otherwise, regular EGA is used. This method was validated Christensen's (2022) <i>PsyArXiv</i> simulation. Consensus clustering can be used by specifying either "consensus.method" or "consensus.iter"

Numeric (length = 1). Number of replicate samples to be drawn from a mul- tivariate normal distribution (uses MASS::mvrnorm). Defaults to 100 (recom- mended)
Numeric (length = 1). Defaults to NULL or random results. Set for reproducible results. See Reproducibility and PRNG for more details on random number generation in EGAnet

verbose	Boolean (length = 1). Should progress be displayed? Defaults to TRUE. Set to
	FALSE to not display progress

Additional arguments that can be passed on to auto.correlate, network.estimation, . . . community.detection, community.consensus, and EGA

Value

Returns a list containing:

empirical	Prediction of model based on empirical dataset only
bootstrap	Prediction of model based on means of the loadings across the bootstrap repli- cate samples
proportion	Proportions of models suggested across bootstraps

iter

seed

modularity

Description

Computes (signed) modularity statistic given a network and community structure. Allows the resolution parameter to be set

Usage

```
modularity(network, memberships, resolution = 1, signed = FALSE)
```

Arguments

network	Matrix or data frame. A symmetric matrix representing a network
memberships	Numeric (length = ncol(network)). A numeric vector of integer values corresponding to each node's community membership
resolution	Numeric (length = 1). A parameter that adjusts modularity to prefer smaller (resolution > 1) or larger ($0 < resolution < 1$) communities. Defaults to 1 (standard modularity computation)
signed	Boolean (length = 1). Whether signed or absolute modularity should be com- puted. The most common modularity metric is defined by positive values only. Gomez et al. (2009) introduced a signed version of modularity that will discount modularity for edges with negative values. This property isn't always desired for psychometric networks. If TRUE, then this signed modularity metric will be com- puted. If FALSE, then the absolute value of the edges in the network (using abs) will be used to compute modularity. Defaults to FALSE

Value

Returns the modularity statistic

Author(s)

Alexander P. Christensen <alexpaulchristensen@gmail.com> with assistance from GPT-4

References

Examples

```
# Load data
wmt <- wmt2[,7:24]</pre>
# Estimate EGA
ega.wmt <- EGA(wmt, model = "glasso")</pre>
# Compute standard (absolute values) modularity
modularity(
  network = ega.wmt$network,
 memberships = ega.wmt$wc,
  signed = FALSE
)
# 0.1697952
# Compute signed modularity
modularity(
  network = ega.wmt$network,
  memberships = ega.wmt$wc,
  signed = TRUE
)
# 0.1701946
```

net.loads Network Loadings

Description

Computes the between- and within-community strength of each variable for each community

Usage

```
net.loads(
    A,
    wc,
    loading.method = c("original", "revised"),
    scaling = 2,
    rotation = NULL,
    ...
)
```

Arguments

A	Network matrix, data frame, or EGA object
WC	Numeric or character vector (length = ncol(A)). A vector of community assign-
	ments. If input into A is an EGA object, then we is automatically detected

net.loads

loading.method	Character (length = 1). Sets network loading calculation based on implementa-
	tion described in "original" (Christensen & Golino, 2021) or the "revised"
	(Christensen et al., 2024) implementation. Defaults to "revised"
scaling	Numeric (length = 1). Scaling factor for the magnitude of the "experimental" network loadings. Defaults to 2. 10 makes loadings roughly the size of factor loadings when correlations between factors are orthogonal
rotation	Character. A rotation to use to obtain a simpler structure. For a list of rota- tions, see rotations for options. Defaults to NULL or no rotation. By setting a rotation, scores estimation will be based on the rotated loadings rather than unrotated loadings
	Additional arguments to pass on to rotations

Details

Simulation studies have demonstrated that a node's strength centrality is roughly equivalent to factor loadings (Christensen & Golino, 2021; Hallquist, Wright, & Molenaar, 2019). Hallquist and colleagues (2019) found that node strength represented a combination of dominant and cross-factor loadings. This function computes each node's strength within each specified dimension, providing a rough equivalent to factor loadings (including cross-loadings; Christensen & Golino, 2021).

Value

Returns a list containing:

unstd	A matrix of the unstandardized within- and between-community strength values for each node
std	A matrix of the standardized within- and between-community strength values for each node
rotated	NULL if rotation = NULL; otherwise, a list containing the rotated standardized network loadings (loadings) and correlations between dimensions (Phi) from the rotation

Author(s)

Alexander P. Christensen <alexpaulchristensen@gmail.com> and Hudson Golino <hfg9s at virginia.edu>

Christensen, A. P., Golino, H., Abad, F. J., & Garrido, L. E. (2024). Revised network loadings. *PsyArXiv*.

Examples

```
# Load data
wmt <- wmt2[,7:24]
# Estimate EGA
ega.wmt <- EGA(
   data = wmt,
   plot.EGA = FALSE # No plot for CRAN checks
)
# Network loadings
net.loads(ega.wmt)</pre>
```

Network Scores

net.scores

Description

This function computes network scores computed based on each node's strength within each community in the network (see net.loads). These values are used as "network loadings" for the weights of each variable.

Network scores are computed as a formative composite rather than a reflective factor. This composite representation is consistent with no latent factors that psychometric network theory proposes.

Scores can be computed as a "simple" structure, which is equivalent to a weighted sum scores or as a "full" structure, which is equivalent to an EFA approach. Conservatively, the "simple" structure approach is recommended until further validation

Usage

```
net.scores(
  data,
  A,
  wc,
  loading.method = c("original", "revised"),
  rotation = NULL,
  scores = c("Anderson", "Bartlett", "components", "Harman", "network", "tenBerge",
    "Thurstone"),
  loading.structure = c("simple", "full"),
  impute = c("mean", "median", "none"),
  ...
)
```

Arguments

data	Matrix or data frame. Should consist only of variables to be used in the analysis
A	Network matrix, data frame, or EGA object

net.scores

WC	Numeric or character vector (length = $ncol(A)$). A vector of community assignments. If input into A is an EGA object, then wc is automatically detected	
loading.method	Character (length = 1). Sets network loading calculation based on implementa- tion described in "original" (Christensen & Golino, 2021) or the "revised" (Christensen et al., 2024) implementation. Defaults to "revised"	
rotation	Character. A rotation to use to obtain a simpler structure. For a list of rota- tions, see rotations for options. Defaults to NULL or no rotation. By setting a rotation, scores estimation will be based on the rotated loadings rather than unrotated loadings	
scores	Character (length = 1). How should scores be estimated? Defaults to "network" for network scores. Set to other scoring methods which will be computed using factor.scores (see link for arguments and explanations for other methods)	
loading.structu	lre	
	Character (length = 1). Whether simple structure or the saturated loading matrix should be used when computing scores. Defaults to "simple"	
	"simple" structure more closely mirrors sum scores and CFA; "full" structure more closely mirrors EFA	
	Simple structure is the more "conservative" (established) approach and is there- fore the default. Treat "full" as experimental as proper vetting and validation has not been established	
impute	Character (length = 1). If there are any missing data, then imputation can be implemented. Available options:	
	 "none" — Default. No imputation is performed 	
	• "mean" — The mean value of each variable is used to replace missing data for that variable	
	• "median" — The median value of each variable is used to replace missing data for that variable	
	Additional arguments to be passed on to net.loads and factor.scores	

Value

Returns a list containing:

scores	A list containing the standardized (std.scores) rotated (rot.scores) scores.
	If rotation = NULL, then rot.scores will be NULL
loadings	Output from net.loads

Author(s)

Alexander P. Christensen <alexpaulchristensen@gmail.com> and Hudson F. Golino <hfg9s at virginia.edu>

network.compare	Compares Network Structure	s Using Permutation
-----------------	----------------------------	---------------------

Description

A permutation implementation to determine statistical significance of whether the network structures are different from one another

Usage

```
network.compare(
    base,
    comparison,
    corr = c("auto", "cor_auto", "pearson", "spearman"),
    na.data = c("pairwise", "listwise"),
    model = c("BGGM", "glasso", "TMFG"),
    iter = 1000,
    ncores,
    verbose = TRUE,
    seed = NULL,
    ....
)
```

Arguments

base	Matrix or data frame. Should consist only of variables to be used in the analysis. First dataset
comparison	Matrix or data frame. Should consist only of variables to be used in the analysis. Second dataset
corr	Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:
	 "auto" — Automatically computes appropriate correlations for the data using Pearson's for continuous, polychoric for ordinal, tetrachoric for binary, and polyserial/biserial for ordinal/binary with continuous. To change the number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details) "cor_auto" — Uses cor_auto to compute correlations. Arguments can be passed along to the function
	 pear son — Pearson's correlation is computed for all variables regardless of categories "spearman" — Spearman's rank-order correlation is computed for all variables regardless
	ables regardless of categories
	For other similarity measures, compute them first and input them into data with the sample size (n)
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
	 "pairwise" — Computes correlation for all available cases between two variables
	• "listwise" — Computes correlation for all complete cases in the dataset
model	Character (length = 1). Defaults to "glasso". Available options:
	 "BGGM" — Computes the Bayesian Gaussian Graphical Model. Set argument ordinal.categories to determine levels allowed for a variable to be considered ordinal. See ?BGGM::estimate for more details "glasso" — Computes the GLASSO with EBIC model selection. See EBICglasso.qgraph for more details
	• "TMFG" — Computes the TMFG method. See TMFG for more details
iter	Numeric (length = 1). Number of permutations to perform. Defaults to 1000 (recommended)
ncores	Numeric (length = 1). Number of cores to use in computing results. Defaults to ceiling(parallel::detectCores() / 2) or half of your computer's process- ing power. Set to 1 to not use parallel computing
verbose	Boolean (length = 1). Should progress be displayed? Defaults to TRUE. Set to FALSE to not display progress
seed	Numeric (length = 1). Defaults to NULL or random results. Set for reproducible results. See Reproducibility and PRNG for more details on random number generation in EGAnet
	Additional arguments that can be passed on to auto.correlate, network.estimation, community.detection, community.consensus, EGA, and jsd

Value

Returns a list:	
network	Data frame with row names of each measure, empirical value (statistic), and <i>p</i> -value based on the permutation test (p.value)
edges	List containing matrices of values for empirical values (statistic), <i>p</i> -values (p.value), and Benjamini-Hochberg corrected <i>p</i> -values (p.adjusted)

network.estimation Apply a Network Estimation Method

Description

General function to apply network estimation methods in EGAnet

Usage

```
network.estimation(
    data,
    n = NULL,
    corr = c("auto", "cor_auto", "cosine", "pearson", "spearman"),
    na.data = c("pairwise", "listwise"),
    model = c("BGGM", "glasso", "TMFG"),
    network.only = TRUE,
    verbose = FALSE,
    ...
)
```

Arguments

Matrix or data frame. Should consist only of variables to be used in the analysis
Numeric (length = 1). Sample size if data provided is a correlation matrix
Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:
• "auto" — Automatically computes appropriate correlations for the data us- ing Pearson's for continuous, polychoric for ordinal, tetrachoric for binary, and polyserial/biserial for ordinal/binary with continuous. To change the number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details)
• "cor_auto" — Uses cor_auto to compute correlations. Arguments can be passed along to the function
 "cosine" — Uses cosine to compute cosine similarity
• "pearson" — Pearson's correlation is computed for all variables regardless of categories
• "spearman" — Spearman's rank-order correlation is computed for all vari- ables regardless of categories
For other similarity measures, compute them first and input them into data with the sample size (n)
Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
• "pairwise" — Computes correlation for all available cases between two variables

	• "listwise" — Computes correlation for all complete cases in the dataset
model	Character (length = 1). Defaults to "glasso". Available options:
	• "BGGM" — Computes the Bayesian Gaussian Graphical Model. Set argument ordinal.categories to determine levels allowed for a variable to be considered ordinal. See ?BGGM::estimate for more details
	• "glasso" — Computes the GLASSO with EBIC model selection. See EBICglasso.qgraph for more details
	• "TMFG" — Computes the TMFG method. See TMFG for more details
network.only	Boolean (length = 1). Whether the network only should be output. Defaults to TRUE. Set to FALSE to obtain all output for the network estimation method
verbose	Boolean (length = 1). Whether messages and (insignificant) warnings should be output. Defaults to FALSE (silent calls). Set to TRUE to see all messages and warnings for every function call
	Additional arguments to be passed on to auto.correlate and the different net- work estimation methods (see model for model specific details)

Value

Returns a matrix populated with a network from the input data

network.nonconvex GLASSO with Non-convex Penalties

Description

The graphical least absolute shrinkage and selection operator with a non-convex regularization penalties

Usage

```
network.nonconvex(
  data,
  n = NULL,
  corr = c("auto", "cor_auto", "cosine", "pearson", "spearman"),
  na.data = c("pairwise", "listwise"),
  penalty = c("iPOT", "LGP", "POP", "SPOT"),
  gamma = NULL,
  lambda = NULL,
  nlambda = 50,
  lambda.min.ratio = 0.01,
 penalize.diagonal = TRUE,
 optimize.over = c("none", "lambda", "both"),
  ic = c("AIC", "AICc", "BIC", "EBIC"),
  ebic.gamma = 0.5,
  fast = TRUE,
  verbose = FALSE,
  . . .
)
```

Arguments

data	Matrix or data frame. Should consist only of variables to be used in the analysis	
n	Numeric (length = 1). Sample size must be provided if data provided is a correlation matrix	
corr	Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:	
	• "auto" — Automatically computes appropriate correlations for the data us- ing Pearson's for continuous, polychoric for ordinal, tetrachoric for binary, and polyserial/biserial for ordinal/binary with continuous. To change the	

		number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details)
		• "cor_auto" — Uses cor_auto to compute correlations. Arguments can be passed along to the function
		• "cosine" — Uses cosine to compute cosine similarity
		• "pearson" — Pearson's correlation is computed for all variables regardless of categories
		 "spearman" — Spearman's rank-order correlation is computed for all variables regardless of categories
		For other similarity measures, compute them first and input them into data with the sample size (n)
	na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
		• "pairwise" — Computes correlation for all available cases between two variables
		• "listwise" — Computes correlation for all complete cases in the dataset
	penalty	Character (length = 1). Available options:
		• "iPOT" — Inverse power of two
		 "LGP" — Lambda-gamma power
		• "POP" — Plus one Pareto
		• "SPOT" — Sigmoid power of two (default)
	gamma	Numeric (length = 1). Adjusts the shape of the penalty. Defaults:
		• "iPOT" = 5
		• "LGP" = 5
		• "POP" = 4
		• "SPOT" = 3
	lambda	Numeric (length = 1). Adjusts the initial penalty provided to the non-convex penalty function
	nlambda	Numeric (length = 1). Number of lambda values to test. Defaults to 100
lambda.min.ratio		io
	unualiza diana	Numeric (length = 1). Ratio of lowest lambda value compared to maximal lambda. Defaults to 0.01
	penalize.diagor	Boolean (length = 1). Should the diagonal be penalized? Defaults to FALSE
	optimize.over	Character (length = 1). Whether optimization of lambda, gamma, both, or no hyperparamters should be performed. Defaults to "none" or no optimization
	ic	Character (length = 1). What information criterion should be used for model selection? Available options include:
		• "AIC" — Akaike's information criterion: $-2L + 2E$
		• "AICc" — AIC corrected: $AIC + \frac{2E^2 + 2E}{n-E-1}$
		• "BIC" — Bayesian information criterion: $-2L + E \cdot \log(n)$
		• "EBIC" — Extended BIC: $BIC + 4E \cdot \gamma \cdot \log(E)$

Term definitions:

 <i>n</i> — sample 	e size
---------------------------------------	--------

- p number of variables
- E edges
- S empirical correlation matrix
- *K* estimated inverse covariance matrix (network)
- $L = \frac{n}{2} \cdot \log \det K \sum_{i=1}^{p} (SK)_{ii}$

Defaults to "BIC"

ebic.gamma	Numeric (length = 1) Value to set gamma parameter in EBIC (see above). De- faults to 0.50 Only used if ic = "EBIC"
fast	Boolean (length = 1). Whether the glassoFast version should be used to esti- mate the GLASSO. Defaults to TRUE.
	The fast results <i>may</i> differ by less than floating point of the original GLASSO implemented by glasso and should not impact reproducibility much (set to FALSE if concerned)
verbose	Boolean (length = 1). Whether messages and (insignificant) warnings should be output. Defaults to FALSE (silent calls). Set to TRUE to see all messages and warnings for every function call
	Additional arguments to be passed on to auto.correlate

Value

A network matrix

Author(s)

Alexander P. Christensen <alexpaulchristensen at gmail.com> and Hudson Golino <hfg9s at virginia.edu>

```
# Obtain data
wmt <- wmt2[,7:24]
# Obtain network
awe_network <- network.nonconvex(data = wmt)</pre>
```

network.predictability

Predict New Data based on Network

Description

General function to compute a network's predictive power on new data, following Haslbeck and Waldorp (2018) and Williams and Rodriguez (2022)

This implementation is different from the predictability in the mgm package (Haslbeck), which is based on (regularized) regression. This implementation uses the network directly, converting the partial correlations into an implied precision (inverse covariance) matrix. See **Details** for more information

Usage

```
network.predictability(network, original.data, newdata, ordinal.categories = 7)
```

Arguments

network	Matrix or data frame. A partial correlation network	
original.data	Matrix or data frame. Must consist only of variables to be used to estimate the network. See Examples	
newdata	Matrix or data frame. Must consist of the same variables in the same order as original.data. See Examples	
ordinal.categories		
	Numeric (length = 1). $Up \ to$ the number of categories <i>before</i> a variable is considered continuous. Defaults to 7 categories before 8 is considered continuous	

Details

This implementation of network predictability proceeds in several steps with important assumptions:

1. Network was estimated using (partial) correlations (not regression like the mgm package!)

2. Original data that was used to estimate the network in 1. is necessary to apply the original scaling to the new data

3. (Linear) regression-like coefficients are obtained by reserve engineering the inverse covariance matrix using the network's partial correlations (i.e., by setting the diagonal of the network to -1 and computing the inverse of the opposite signed partial correlation matrix; see EGAnet:::pcor2inv)

4. Predicted values are obtained by matrix multiplying the new data with these coefficients

5. **Dichotomous and polytomous** data are given categorical values based on the **original data's** thresholds and these thresholds are used to convert the continuous predicted values into their corresponding categorical values

6. Evaluation metrics:

network.predictability

- dichotomous "Accuracy" or the percent correctly predicted for the 0s and 1s and "Kappa" or Cohen's Kappa (see cite)
- polytomous "Linear Kappa" or linearly weighted Kappa and "Krippendorff's alpha" (see cite)
- continuous R-squared ("R2") and root mean square error ("RMSE")

Value

Returns a list containing:

predictions	Predicted values of newdata based on the network
betas	Beta coefficients derived from the network
results	Performance metrics for each variable in newdata

Author(s)

Hudson Golino <hfg9s at virginia.edu> and Alexander P. Christensen <alexpaulchristensen@gmail.com>

```
# Load data
wmt <- wmt2[,7:24]
# Set seed (to reproduce results)
set.seed(42)
# Split data
training <- sample(
    1:nrow(wmt), round(nrow(wmt) * 0.80) # 80/20 split
)</pre>
```

optimism

```
# Set splits
wmt_train <- wmt[training,]
wmt_test <- wmt[-training,]
# EBICglasso (default for EGA functions)
glasso_network <- network.estimation(
    data = wmt_train, model = "glasso"
)
# Check predictability
network.predictability(
    network = glasso_network, original.data = wmt_train,
    newdata = wmt_test
)</pre>
```

optimism

Optimism Data

Description

A response matrix (n = 282) containing responses to 10 items of the Revised Life Orientation Test (LOT-R), developed by Scheier, Carver, & Bridges (1994).

Usage

data(optimism)

Format

A 282x10 response matrix

References

Scheier, M. F., Carver, C. S., & Bridges, M. W. (1994). Distinguishing optimism from neuroticism (and trait anxiety, self-mastery, and self-esteem): a reevaluation of the Life Orientation Test. *Journal of Personality and Social Psychology*, *67*, 1063-1078.

Examples

data("optimism")
Description

A fast implementation of polychoric correlations in C. Uses the Beasley-Springer-Moro algorithm (Boro & Springer, 1977; Moro, 1995) to estimate the inverse univariate normal CDF, the Drezner-Wesolosky approximation (Drezner & Wesolosky, 1990) to estimate the bivariate normal CDF, and Brent's method (Brent, 2013) for optimization of rho

Usage

```
polychoric.matrix(
   data,
   na.data = c("pairwise", "listwise"),
   empty.method = c("none", "zero", "all"),
   empty.value = c("none", "point_five", "one_over"),
   ...
)
```

data	Matrix or data frame. A dataset with all ordinal values (rows = cases, columns = variables). Data are required to be between 0 and 11. Proper adjustments should be made prior to analysis (e.g., scales from -3 to 3 in increments of 1 should be shifted by added 4 to all values)
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
	 "pairwise" — Computes correlation for all available cases between two variables "listwise" — Computes correlation for all complete cases in the dataset
empty.method	Character (length = 1). Method for empty cell correction. Available options:
	 "none" — Adds no value (empty.value = "none") to the empirical joint frequency table between two variables "zero" — Adds empty value to the cells with zero in the joint frequency.
	table between two variables
	• "all" — Adds empty.value to all in the joint frequency table between two variables
empty.value	Character (length = 1). Value to add to the joint frequency table cells. Accepts numeric values between 0 and 1 or specific methods:
	 "none" — Adds no value (0) to the empirical joint frequency table between two variables
	 "point_five" — Adds 0.5 to the cells defined by empty.method

- "one_over" Adds 1 / n where n equals the number of cells based on empty.method. For empty.method = "zero", n equals the number of zero cells
- Not used but made available for easier argument passing

Value

. . .

Returns a polychoric correlation matrix

Author(s)

Alexander P. Christensen <alexpaulchristensen@gmail.com> with assistance from GPT-4

Examples

```
# Load data (ensure matrix for missing data example)
wmt <- as.matrix(wmt2[,7:24])</pre>
```

```
# Compute polychoric correlation matrix
correlations <- polychoric.matrix(wmt)</pre>
```

Randomly assign missing data
wmt[sample(1:length(wmt), 1000)] <- NA</pre>

```
# Compute polychoric correlation matrix
# with pairwise missing
pairwise_correlations <- polychoric.matrix(
   wmt, na.data = "pairwise"
)</pre>
```

```
# Compute polychoric correlation matrix
# with listwise missing
pairwise_correlations <- polychoric.matrix(
   wmt, na.data = "listwise"
)</pre>
```

prime.num

Description

Numeric vector of primes generated from the primes package. Used in the function [EGAnet]{ergoInfo}. Not for general use

Usage

data(prime.num)

Format

A 1185x24 response matrix

Examples

data("prime.num")

riEGA

Random-Intercept EGA

Description

Estimates the number of substantive dimensions after controlling for wording effects. EGA is applied to a residual correlation matrix after subtracting and random intercept factor with equal unstandardized loadings from all the regular and unrecoded reversed items in the database

Usage

```
riEGA(
    data,
    n = NULL,
    corr = c("auto", "cor_auto", "cosine", "pearson", "spearman"),
    na.data = c("pairwise", "listwise"),
    model = c("glasso", "TMFG"),
    algorithm = c("leiden", "louvain", "walktrap"),
    uni.method = c("expand", "LE", "louvain"),
    plot.EGA = TRUE,
    verbose = FALSE,
    ...
)
```

data	Matrix or data frame. Should consist only of variables to be used in the analysis. Must be raw data and not a correlation matrix
n	Numeric (length = 1). Sample size if data provided is a correlation matrix
corr	Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:
	• "auto" — Automatically computes appropriate correlations for the data us- ing Pearson's for continuous, polychoric for ordinal, tetrachoric for binary, and polyserial/biserial for ordinal/binary with continuous. To change the number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details)
	• "cor_auto" — Uses cor_auto to compute correlations. Arguments can be passed along to the function
	 "cosine" — Uses cosine to compute cosine similarity
	 "pearson" — Pearson's correlation is computed for all variables regardless of categories
	 "spearman" — Spearman's rank-order correlation is computed for all variables regardless of categories
	For other similarity measures, compute them first and input them into data with the sample size (n)
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
	 "pairwise" — Computes correlation for all available cases between two variables
	• "listwise" — Computes correlation for all complete cases in the dataset
model	Character (length = 1). Defaults to "glasso". Available options:
	 "BGGM" — Computes the Bayesian Gaussian Graphical Model. Set argument ordinal.categories to determine levels allowed for a variable to be considered ordinal. See ?BGGM::estimate for more details "glasso" — Computes the GLASSO with EBIC model selection. See EBICglasso.qgraph for more details
	• "TMFG" — Computes the TMFG method. See TMFG for more details
algorithm	Character or igraph cluster_* function (length = 1). Defaults to "walktrap". Three options are listed below but all are available (see community.detection for other options):
	 "leiden" — See cluster_leiden for more details "louvain" — By default, "louvain" will implement the Louvain algorithm using the consensus clustering method (see community.consensus for more information). This function will implement consensus.method = "most_common" and consensus.iter = 1000 unless specified otherwise "walktrap" — See cluster_walktrap for more details
uni.method	Character (length = 1). What unidimensionality method should be used? De- faults to "louvain". Available options:

	• "expand" — Expands the correlation matrix with four variables correlated 0.50. If number of dimension returns 2 or less in check, then the data are unidimensional; otherwise, regular EGA with no matrix expansion is used. This method was used in the Golino et al.'s (2020) <i>Psychological Methods</i> simulation
	• "LE" — Applies the Leading Eigenvector algorithm (cluster_leading_eigen) on the empirical correlation matrix. If the number of dimensions is 1, then the Leading Eigenvector solution is used; otherwise, regular EGA is used. This method was used in the Christensen et al.'s (2023) <i>Behavior Research</i> <i>Methods</i> simulation
	• "louvain" — Applies the Louvain algorithm (cluster_louvain) on the empirical correlation matrix. If the number of dimensions is 1, then the Louvain solution is used; otherwise, regular EGA is used. This method was validated Christensen's (2022) <i>PsyArXiv</i> simulation. Consensus clustering can be used by specifying either "consensus.method" or "consensus.iter"
plot.EGA	Boolean (length = 1). If TRUE, returns a plot of the network and its estimated dimensions. Defaults to TRUE
verbose	Boolean (length = 1). Whether messages and (insignificant) warnings should be output. Defaults to FALSE (silent calls). Set to TRUE to see all messages and warnings for every function call
	Additional arguments to be passed on to auto.correlate, network.estimation, community.detection, community.consensus, and EGA

Value

Returns a list containing:

EGA	Results from EGA
RI	A list containing information about the random-intercept model (if the model converged):
	• fit — The fit object for the random-intercept model using cfa
	• lavaan.args — The arguments used in cfa
	• loadings — Standardized loadings from the random-intercept model
	• correlation — Residual correlations after accounting for the random- intercept model
TEFI	link[EGAnet]{tefi} for the estimated structure
plot.EGA	Plot output if plot.EGA = TRUE

sim.dynEGA

sim.dynEGA Data

Description

A simulated (multivariate time series) data with 24 variables, 100 individual observations, 50 time points per individual and 2 groups of individuals

Usage

data(sim.dynEGA)

Format

A 5000 x 26 multivariate time series

Details

Data were generated using the simDFM function with the following arguments:

Group 1

```
simDFM( variab = 12, timep = 50, nfact = 2, error = 0.125, dfm = "DAFS", loadings = EGAnet:::runif_xoshiro(
1, min = 0.50, max = 0.70), autoreg = 0.80, crossreg = 0.00, var.shock = 0.36, cov.shock
= 0.18)
```

Group 2

```
simDFM( variab = 8, timep = 50, nfact = 3, error = 0.125, dfm = "DAFS", loadings = EGAnet:::runif_xoshiro(
1, min = 0.50, max = 0.70), autoreg = 0.80, crossreg = 0.00, var.shock = 0.36, cov.shock
= 0.18)
```

Examples

data("sim.dynEGA")

simDFM

Simulate data following a Dynamic Factor Model

Description

Function to simulate data following a dynamic factor model (DFM). Two DFMs are currently available: the direct autoregressive factor score model (Engle & Watson, 1981; Nesselroade, McArdle, Aggen, and Meyers, 2002) and the dynamic factor model with random walk factor scores.

Usage

```
simDFM(
  variab,
  timep,
  nfact,
  error,
  dfm = c("DAFS", "RandomWalk"),
  loadings,
  autoreg,
  crossreg,
  var.shock,
  cov.shock,
  burnin = 1000
}
```

```
)
```

variab	Number of variables per factor.
timep	Number of time points.
nfact	Number of factors.
error	Value to be used to construct a diagonal matrix Q . This matrix is p x p covariance matrix Q that will generate random errors following a multivariate normal distribution with mean zeros. The value provided is squared before constructing Q .
dfm	A string indicating the dynamical factor model to use. Current options are:
	• DAFS — Simulates data using the direct autoregressive factor score model. This is the default method
	• RandomWalk — Simulates data using a dynamic factor model with random walk factor scores
loadings	Magnitude of the loadings.

autoreg	Magnitude of the autoregression coefficients.
crossreg	Magnitude of the cross-regression coefficients.
var.shock	Magnitude of the random shock variance.
cov.shock	Magnitude of the random shock covariance
burnin	Number of n first samples to discard when computing the factor scores. Defaults
	to 1000.

Examples

```
## Not run:
# Estimate EGA network
data1 <- simDFM(variab = 5, timep = 50, nfact = 3, error = 0.05,
dfm = "DAFS", loadings = 0.7, autoreg = 0.8,
crossreg = 0.1, var.shock = 0.36,
cov.shock = 0.18, burnin = 1000)
## End(Not run)
```

simEGM

Simulate data following a Exploratory Graph Model (EGM)

Description

Function to simulate data based on EGM

Usage

```
simEGM(
   communities,
   variables,
   loadings,
   cross.loadings = 0.02,
   correlations,
   sample.size,
   max.iterations = 1000
)
```

Arguments

communities	Numeric (length = 1). Number of communities to generate
variables	Numeric vector (length = 1 or communities). Number of variables per community
loadings	Numeric (length = 1). Magnitude of the assigned network loadings. For reference, small (0.20) , moderate (0.35) , and large (0.50)
	Uses runif(n, min = value - 0.075, max = value + 0.075) for some jitter in the loadings
cross.loadings	Numeric (length = 1). Standard deviation of a normal distribution with a mean of zero (n, mean = 0 , sd = value). Defaults to 0.02 . Not recommended to change too drastically (small increments such as 0.01 work best)
correlations	Numeric (length = 1). Magnitude of the community correlations
sample.size	Numeric (length = 1). Number of observations to generate
max.iterations	Numeric (length = 1). Number of iterations to attempt to get convergence before erroring out. Defaults to 1000

Author(s)

Hudson F. Golino <hfg9s at virginia.edu> and Alexander P. Christensen <alexpaulchristensen@gmail.com>

Examples

```
simulated <- simEGM(
   communities = 2, variables = 6,
   loadings = 0.55, # use standard factor loading sizes
   correlations = 0.30,
   sample.size = 1000
)</pre>
```

tefi

Total Entropy Fit Index using Von Neumman's entropy (Quantum Information Theory) for correlation matrices

Description

Computes the fit (TEFI) of a dimensionality structure using Von Neumman's entropy when the input is a correlation matrix. Lower values suggest better fit of a structure to the data.

Usage

tefi(data, structure = NULL, verbose = TRUE)

Arguments

data	Matrix, data frame, or *EGA class object. Matrix or data frame can be raw data or a correlation matrix. All *EGA objects are accepted. hierEGA input will pro- duced the Generalized TEFI (see genTEFI)
structure	Numeric or character vector (length = ncol(data)). Can be theoretical factors or the structure detected by EGA
verbose	Boolean (length = 1). Whether messages and (insignificant) warnings should be output. Defaults to TRUE to see all messages and warnings for every function call. Set to FALSE to ignore messages and warnings

Value

Returns a data frame with columns:

Non-hierarchical Structure

VN. Entropy. Fit The Total Entropy Fit Index using Von Neumman's entropy

Total.Correlation

The total correlation of the dataset

Average.Entropy

The average entropy of the dataset

Hierarchical Structure

VN.Entropy.Fit The Generalized Total Entropy Fit Index using Von Neumman's entropy

Lower.Order.VN Lower order (only) Total Entropy Fit Index Higher.Order.VN

Higher order (only) Total Entropy Fit Index

Author(s)

Hudson Golino <hfg9s at virginia.edu>, Alexander P. Christensen <alexpaulchristensen@gmail.com>, and Robert Moulder <rgm4fd@virginia.edu>

References

Initial formalization and simulation

Golino, H., Moulder, R. G., Shi, D., Christensen, A. P., Garrido, L. E., Nieto, M. D., Nesselroade, J., Sadana, R., Thiyagarajan, J. A., & Boker, S. M. (2020). Entropy fit indices: New fit measures for assessing the structure and dimensionality of multiple latent variables. *Multivariate Behavioral Research*.

Examples

```
# Load data
wmt <- wmt2[,7:24]
# Estimate EGA model
ega.wmt <- EGA(</pre>
```

tefi.compare

```
data = wmt, model = "glasso",
  plot.EGA = FALSE # no plot for CRAN checks
)
# Compute entropy indices for empirical EGA
tefi(ega.wmt)
# User-defined structure (with `EGA` object)
tefi(ega.wmt, structure = c(rep(1, 5), rep(2, 5), rep(3, 8)))
```

tefi.compare

Compare Total Entropy Fit Index (tefi) Between Two Structures

Description

This function computes the tefi values for two different structures using bootstrapped correlation matrices from bootEGA and compares them using a non-parametric bootstrap test. It also visualizes the distributions of tefi values for both structures.

Usage

```
tefi.compare(bootega.obj, base, comparison, plot.TEFI = TRUE, ...)
```

Arguments

bootega.obj	A bootEGA object
base	Numeric (length = columns in original dataset). A vector representing the base structure to be tested
comparison	Numeric (length = columns in original dataset). A vector representing the struc- ture to be compared against the base structure
plot.TEFI	Boolean (length = 1). Whether the TEFI comparison and the p-value should be plotted. Defaults to TRUE
	Additional arguments that can be passed on to plot.EGAnet. See Examples for plotting arguments

Details

The null hypothesis is that the TEFI values obtained in the bootstrapped correlation matrices for the base structure are than the TEFI values obtained in the bootstrapped correlation matrices for the comparison structure. Therefore, the *p*-value in this bootstrap test can be interpreted as follows:

- If the *p*-value less than 0.05: TEFI values for the base structure tend to be lower than the comparison structure, indicating that the former provides a better fit (lower entropy) than the latter
- If the *p*-value is greater than 0.05: TEFI values for the base structure are not significantly lower than the comparison structure, suggesting that both structures may provide similar fits or that comparison might fit better

Value

A list containing:

TEFI.df	A data frame containing the TEFI values for both structures
p.value	The p -value from the non-parametric bootstrap hypothesis test

Author(s)

Hudson Golino <hfg9s at virginia.edu> and Alexander P. Christensen <alexpaulchristensen@gmail.com>

Examples

```
# Obtain data
wmt <- wmt2[,7:24]</pre>
## Not run:
# Perform bootstrap EGA
boot.wmt <- bootEGA(</pre>
  data = wmt, iter = 500,
  type = "parametric", ncores = 2
)
## End(Not run)
# Perform comparison
comparing_tefi <- tefi.compare(</pre>
  boot.wmt,
  base = boot.wmt$EGA$wc, # Compare Walktrap
  comparison = community.detection(
   boot.wmt$EGA$network, algorithm = "louvain"
  ) # With Louvain
)
# Plot options (UVa colors)
plot(
  comparing_tefi,
  base.name = "Walktrap", base.color = "#232D4B",
  comparison.name = "Louvain", comparison.color = "#E57200"
)
```

TMFG

Triangulated Maximally Filtered Graph

Description

Applies the Triangulated Maximally Filtered Graph (TMFG) filtering method (see Massara et al., 2016). The TMFG method uses a structural constraint that limits the number of zero-order correlations included in the network (3n - 6; where *n* is the number of variables). The TMFG algorithm begins by identifying four variables which have the largest sum of correlations to all other variables.

120

TMFG

Then, it iteratively adds each variable with the largest sum of three correlations to nodes already in the network until all variables have been added to the network. This structure can be associated with the inverse correlation matrix (i.e., precision matrix) to be turned into a GGM (i.e., partial correlation network) by using Local-Global Inversion Method (LoGo; see Barfuss et al., 2016 for more details). See **Details** for more information

Usage

```
TMFG(
    data,
    n = NULL,
    corr = c("auto", "cor_auto", "cosine", "pearson", "spearman"),
    na.data = c("pairwise", "listwise"),
    partial = FALSE,
    returnAllResults = FALSE,
    verbose = FALSE,
    ...
)
```

data	Matrix or data frame. Should consist only of variables to be used in the analysis. Can be raw data or correlation matrix
n	Numeric (length = 1). Sample size for when a correlation matrix is input into data. Defaults to NULL. n is not necessary and is provided for better functionality in EGAnet
corr	Character (length = 1). Method to compute correlations. Defaults to "auto". Available options:
	 "auto" — Automatically computes appropriate correlations for the data using Pearson's for continuous, polychoric for ordinal, tetrachoric for binary, and polyserial/biserial for ordinal/binary with continuous. To change the number of categories that are considered ordinal, use ordinal.categories (see polychoric.matrix for more details) "cor_auto" — Uses cor_auto to compute correlations. Arguments can be passed along to the function "cosine" — Uses cosine to compute cosine similarity "pearson" — Pearson's correlation is computed for all variables regardless
	 of categories "spearman" — Spearman's rank-order correlation is computed for all variables regardless of categories
	For other similarity measures, compute them first and input them into data with the sample size (n)
na.data	Character (length = 1). How should missing data be handled? Defaults to "pairwise". Available options:
	• "pairwise" — Computes correlation for all available cases between two variables

	• Its twise — Computes correlation for an complete cases in the dataset
partial	Boolean (length = 1). Whether partial correlations should be output. Defaults to FALSE. The TMFG method is based on the zero-order correlations; the Local-Global Inversion Method (LoGo; see Barfuss et al., 2016 for more details) uses the decomposability of the TMFG network to obtain the inverse covariance structure of the network (which is then converted to partial correlations). Set to TRUE to obtain the partial correlations from the LoGo method
returnAllResult	ts l
	Boolean (length = 1). Whether all results should be returned. Defaults to FALSE (network only). Set to TRUE to access separators and cliques
verbose	Boolean (length = 1). Whether messages and (insignificant) warnings should be output. Defaults to FALSE (silent calls). Set to TRUE to see all messages and warnings for every function call
	Additional arguments to be passed on to auto.correlate

Details

The TMFG method applies a structural constraint on the network, which restrains the network to retain a certain number of edges (3n-6, where n is the number of nodes; Massara et al., 2016). The network is also composed of 3- and 4-node cliques (i.e., sets of connected nodes; a triangle and tetrahedron, respectively). The TMFG method constructs a network using zero-order correlations and the resulting network can be associated with the inverse covariance matrix (yielding a GGM; Barfuss, Massara, Di Matteo, & Aste, 2016). Notably, the TMFG can use any association measure and thus does not assume the data is multivariate normal.

Construction begins by forming a tetrahedron of the four nodes that have the highest sum of correlations that are greater than the average correlation in the correlation matrix. Next, the algorithm iteratively identifies the node that maximizes its sum of correlations to a connected set of three nodes (triangles) already included in the network and then adds that node to the network. The process is completed once every node is connected in the network. In this process, the network automatically generates what's called a planar network. A planar network is a network that could be drawn on a sphere with no edges crossing (often, however, the networks are depicted with edges crossing; Tumminello, Aste, Di Matteo, & Mantegna, 2005).

Value

Returns a network or list containing:

network	The filtered adjacency matrix
separators	The separators (3-cliques) in the network
cliques	The cliques (4-cliques) in the network

totalCor

Total Correlation

Description

Computes the total correlation of a dataset

Usage

totalCor(data, base = 2.718282)

Arguments

data	Matrix or data frame. Should consist only of variables to be used in the analysis
base	Numeric (length = 1). Base to use for entropy. Defaults to exp(1) or 2.718282

Value

Returns a list containing:

Ind.Entropies	Individual entropies for each variable
Joint.Entropy	The joint entropy of the dataset
Total.Cor	The total correlation of the dataset
Normalized	Total correlation divided by the sum of the individual entropies minus the max- imum of the individual entropies

Examples

```
# Compute total correlation
totalCor(wmt2[,7:24])
```

totalCorMat

Total Correlation Matrix

Description

Computes the pairwise total correlation (totalCor) for a dataset

Usage

```
totalCorMat(data, base = 2.718282, normalized = FALSE)
```

Arguments

data	Matrix or data frame. Should consist only of variables to be used in the analysis
base	Numeric (length = 1). Base to use for entropy. Defaults to $exp(1)$ or 2.718282
normalized	Boolean (length = 1). Should the normalized total correlation be computed? Defaults to FALSE

Value

Returns a symmetric matrix with pairwise total correlations

Examples

Compute total correlation matrix totalCorMat(wmt2[,7:24])

UVA

Unique Variable Analysis

Description

Identifies locally dependent (redundant) variables in a multivariate dataset using the EBICglasso.qgraph network estimation method and weighted topological overlap (see Christensen, Garrido, & Golino, 2023 for more details)

Usage

```
UVA(
  data = NULL,
  network = NULL,
  n = NULL,
  key = NULL,
  uva.method = c("MBR", "EJP"),
  cut.off = 0.25,
  reduce = TRUE,
  reduce.method = c("latent", "mean", "remove", "sum"),
  auto = TRUE,
  verbose = FALSE,
  ...
)
```

data	Matrix or data frame. Should consist only of variables to be used in the analysis.
	Can be raw data or a correlation matrix. Defaults to NULL
network	Symmetric matrix or data frame. A symmetric network. Defaults to NULL
	If both data and network are provided, then UVA will use the network with the
	data (rather than estimating a network from the data)

n	Numeric (length = 1). Sample size if data provided is a correlation matrix. Defaults to NULL
key	Character vector (length = ncol(data)). Item key for labeling variables in the results
uva.method	Character (length = 1). Whether the method described in Christensen, Garrido, and Golino (2023) publication in <i>Multivariate Behavioral Research</i> ("MBR") or Christensen, Golino, and Silvia (2020) publication in <i>European Journal of Personality</i> ("EJP") should be used. Defaults to "MBR"
	Based on simulation and accumulating empirical evidence, the methods de- scribed in Christensen, Golino, and Silvia (2020) such as adaptive alpha are outdated . Evidence supports using a single cut-off value (regardless of contin- uous, polytomous, or dichotomous data; Christensen, Garrido, & Golino, 2023)
cut.off	Numeric (length = 1). Cut-off used to determine when pairwise wto values are considered locally dependent (or redundant). Must be values between 0 and 1. Defaults to 0.25
	This cut-off value is recommended and based on extensive simulation (Christensen, Garrido, & Golino, 2023). Printing the result will provide a gradient of pairwise redundancies in increments of 0.20, 0.25, and 0.30. Use print or summary on the output rather than adjusting this cut-off value
reduce	Logical (length = 1). Whether redundancies should be reduced in data. Defaults to TRUE
reduce.method	 Character (length = 1). Method to reduce redundancies. Available options: "latent" — Computes latent variables using cfa when there are three or more redundant variables. If variables are not all coded in the same direction, then they will be recoded as necessary. A warning will be produced for all variables that are flipped "mean" — Computes mean of redundant variables. If variables are not all coded in the same direction, then they same direction, then they will be recoded as necessary. A warning will be produced for all variables that are flipped "remove" — Removes all but one variable from a set of redundant variables "sum" — Computes sum of redundant variables. If variables are not all coded in the same direction, then they will be recoded as necessary. A warning will be produced for all variables that are flipped
auto	 Logical (length = 1). Whether reduce should occur automatically. For reduce.method = "remove", the automated decision process is as follows: Two variables — The variable with the lowest maximum wto to all other variables (other than the one it is redundant with) is retained and the other is removed Three or more variables — The variable with the highest mean wto to all other variables that are redundant with one another is retained and all others are removed
verbose	Boolean (length = 1). Whether messages and (insignificant) warnings should be output. Defaults to FALSE (silent calls). Set to TRUE to see all messages and warnings for every function call
	Additional arguments that should be passed on to old versions of UVA or to EGA and cfa

vn.entropy

Entropy Fit Index using Von Neumman's entropy (Quantum Information Theory) for correlation matrices

Description

Computes the fit of a dimensionality structure using Von Neumman's entropy when the input is a correlation matrix. Lower values suggest better fit of a structure to the data

Usage

```
vn.entropy(data, structure)
```

data	Matrix or data frame. Contains variables to be used in the analysis
structure	Numeric or character vector (length = ncol(data)). A vector representing the structure (numbers or labels for each item). Can be theoretical factors or the
	structure (numbers of labers for each nem). Can be theoretical factors of the
	Subclure delected by EGA

wmt2

Value

Returns a list containing:

VN.Entropy.Fit The Entropy Fit Index using Von Neumman's entropy Total.Correlation The total correlation of the dataset Average.Entropy The average entropy of the dataset

wmt2

WMT-2 Data

Description

A response matrix (n = 1185) of the Wiener Matrizen-Test 2 (WMT-2).

Usage

data(wmt2)

Format

A 1185x24 response matrix

128

Examples

data("wmt2")

wto

Weighted Topological Overlap

Description

Computes weighted topological overlap following the Novick et al. (2009) definition

Usage

wto(network, signed = TRUE, diagonal.zero = TRUE)

Arguments

network	Symmetric matrix or data frame. A symmetric network
signed	Boolean (length = 1). Whether the signed version should be used. Defaults to TRUE. Use FALSE for absolute values
diagonal.zero	Boolean (length = 1). Whether diagonal of overlap matrix should be set to zero. Defaults to TRUE. Use FALSE to allow overlap of a node with itself

Value

A symmetric matrix of weighted topological overlap values between each pair of variables
