Package 'FamEvent'

July 21, 2025

Type Package

Title Family Age-at-Onset Data Simulation and Penetrance Estimation

Version 3.2

Date 2024-07-02

Author Yun-Hee Choi, Karen Kopciuk, Wenqing He, Laurent Briollais

Maintainer Yun-Hee Choi <yun-hee.choi@schulich.uwo.ca>

Description Simulates age-at-onset traits associated with a segregating major gene in family data obtained from population-based, clinic-based, or multi-stage designs. Appropriate ascertainment correction is utilized to estimate age-dependent penetrance functions either parametrically from the fitted model or nonparametrically from the data. The Expectation and Maximization algorithm can infer missing genotypes and carrier probabilities estimated from family's genotype and phenotype information or from a fitted model. Plot functions include pedigrees of simulated families and predicted penetrance curves based on specified parameter values.

`FamEvent-package` *Family age-at-onset data simulation and penetrance estimation*

Description

Family-based studies are used to characterize the disease risk associated with being a carrier of a major gene. When the disease risk can vary with age of onset, penetrance or disease risk functions need to provide age-dependent estimates of this disease risk over lifetime. This FamEvent package can generate age-at-onset data in the context of familial studies, with correction for ascertainment (selection) bias arising from a specified study design based on proband's mutation and disease statuses. Possible study designs are: `"pop"` for population-based design where families are ascertained through affected probands, `"pop+"` are similar to `"pop"` but probands are also known mutation carriers, `"cli"` for clinic-based design that includes affected probands with at least one parent and one sib affected, `"cli+"` are similar to `"cli"` but probands are also known mutation carrriers. And `"twostage"` for two-stage design that randomly samples families from the population in the first stage and oversamples high risk families that includes at least two affected members in the family at the second stage.

Ages at disease onset are generated specific to family members' gender and mutation status according to the specified study design with residual familial correlations induced by a shared frailty, correlated frailties with Kinship matrix, or a second gene.

For estimating age at onset risks with family data, an ascertainment corrected prospective likelihood approach is used to account for the population or clinic-based study designs while a composite likelihood approach is used for the two-stage sampling design. The Expectation and Maximization (EM) algorithm has been implemented for inferring missing genotypes conditional on observed genotypes and phenotypes in the families. For family members who have missing genotypes, their carrier probabilities are obtained either from the fitted model or from Mendelian transmission probabilities.

This package also provides functions to plot the age-dependent penetrance curves estimated parametrically from the fitted model or non-parametrically from the data, pedigree plots of simulated families and penetrance function curves for carriers and non-carriers of a major and second gene based on specified parameter values.

In summary, this package facilitates the following:

1. Family data generations from 1) a shared frailty model or 2) a correlated frailty model with Kinship and/or IBD matrix; 3) a competing risk model.

2. Covariates considered: sex, gene, options for additional covariates.

3. Time-varying covariate generation based on permanent exposure (PE) or the Cox-Oaks model (CO).

3. Model estimation for shared frailty models and competing risk models.

       tvc.parms = c(1, 0.1, 0), allelefreq = 0.02,
       base.parms = c(0.01, 3), vbeta = c(-1.13, 2.35))

summary(fam4)

## End(Not run)
```

carrierprob *Compute mutation carrier probabilities for individuals with missing gentoypes*

Description

Computes model- or data-based carrier probabilities for individuals with missing genotypes based on the observed mutation status of family members and the individual's phenotype.

Usage

```
carrierprob(condition = "geno", method = "data", fit = NULL, data, mode = "dominant",
q = 0.02)
```

Arguments

condition	Choice of conditional information to use for computing the carrier probability. Possible choices are "geno" for using observed genotypes and "geno+pheno" for using both observed genotype and phenotype information in the calculation of the carrier probability.
method	Choice of methods to calculate the carrier probability. Possible choices are "data" for empirical calculation of the carrier probabilities based on data, "mendelian" using Mendelian transmission probabilities based on observed carriers within families, or "model" using the parametric model fit; see details below. Default is "data". If method = "data", only data is required to be specified.
fit	An object of class penmodel, a fitted model by penmodelEM function for inferring missing mutation statuses in the family.
data	Family data that includes missing genotypes using the same data format generated by the function simfam.
mode	Choice of modes of inheritance when using method="model". Possible choices are "dominant" for dominant model or "recessive" for recessive model. Default is "dominant".
q	Frequency of the disease causing allele when using method="model". The value should be between 0 and 1. If NULL, the estimated allele frequency from data will be used. Default value is 0.02.

Details

When method="model" along with the choice of condition="geno+pheno", the carrier probability for individual i is calculated by conditioning on her/his observed phenotype and carrier statuses of family members

$$P(X_i = 1|Y_i, X^o) = \frac{P(Y_i|X_i = 1)P(X_i = 1|X^o)}{P(Y_i|X_i = 1)P(X_i = 1|X^o) + P(Y_i|X_i = 0)P(X_i = 0|X^o)},$$

where X_i indicates the unknown carrier status of individual i and X^o represents the observed carrier statuses in his or her family members; Y_i represents the observed phenotype (t_i, δ_i) of individual i in

terms of age at onset t_i and disease status indicator δ_i with 1 used for affected individuals and 0 for unaffected individuals. When `method="mendelian"` along with the choice of `condition="geno"`, the carrier probability is calculated based on Mendelian laws of genetic transmission with a fixed allele frequency.

Value

Returns a data frame with a vector of carrier probabilities called `carrp.geno` when `condition="geno"` or `carrp.pheno` when `condtion="geno+pheno"` added after the last column of the family data.

             data = fam, mode = "dominant", q = 0.02)

# pedigree plot for family 1 displaying carrier probabilities

plot.simfam(fam.added, famid = 1)
```

`fampower` *Simulation-based power calculation for genetic effect*

Description

Computes the power of detecting genetic effect in the penetrance model based on a family-based simulation study.

Usage

```
fampower(N.fam, N.sim, effectsize, beta.sex, alpha = 0.05, side = 2, design = "pop",
variation = "none", interaction = FALSE, depend = NULL, base.dist = "Weibull",
frailty.dist = NULL, base.parms, allelefreq = c(0.02, 0.2), dominant.m = TRUE,
dominant.s = TRUE, mrate = 0, hr = 0, probandage = c(45, 2), agemin = 20, agemax = 100)
```

Arguments

N.fam	Number of families to generate.
N.sim	Number of simulations.
effectsize	Effect size of the major mutated gene (beta.gene) to detect under the alternative hypothesis. When interaction=TRUE, both the main and interaction effects should be specified, effectsize = c(beta.gene, beta.int).
beta.sex	Gender effect that is fixed in the model.
alpha	Significance level. Default value is 0.05.
side	Number of sides for the alternative hypothesis. Possible choices are 1 for one-sided test and 2 for two-sided test. Default value is 2.
design	Family based study design used in the simulations. Possible choices are: "pop", "pop+", "cli", "cli+" or "twostage", where "pop" is for the population-based design that families are ascertained by affected probands, "pop+" is similar to "pop" but with mutation carrier probands, "cli" is for the clinic-based design that includes affected probands with at least one parent and one sibling affected, "cli+" is similar to "cli" but with mutation carrier probands and "twostage" for two-stage design that randomly samples families from the population in the first stage and oversamples high risk families in the second stage that includes at least two affected members in the family. Default is "pop".
variation	Source of residual familial correlation. Possible choices are: "frailty" for frailty shared within families, "secondgene" for second gene variation, or "none" for no residual familial correlation. Default is "none".
interaction	Logical; if TRUE, the interaction between gender and mutation status is allowed, otherwise no interaction is allowed. Default is FALSE.
depend	Variance of the frailty distribution. Dependence within families increases with depend value. Default value is NULL. Value > 0 should be specified when variation = "frailty".
base.dist	Choice of baseline hazard distribution. Possible choices are: "Weibull", "loglogistic", "Gompertz", "lognormal" "gamma", or "logBurr". Default is "Weibull".
frailty.dist	Choice of frailty distribution. Possible choices are: "gamma" for gamma distribution or "lognormal" for log normal distribution when variation = "frailty". Default is NULL.

base.parms	Vector of parameter values for baseline hazard function. base.parms = c(lambda, rho), where lambda and rho are the shape and scale parameters, respectively. If base.dist = "logBurr" is chosen, three parameters should be specified for base.parms = c(lambda, rho, eta).
allelefreq	Vector of population allele frequencies of major and second disease gene alleles. Frequencies must be between 0 and 1. Default frequencies are 0.02 for major gene allele and 0.2 for second gene allele, allelefreq = c(0.02, 0.2).
dominant.m	Logical; if TRUE, the genetic model of the major gene is dominant, otherwise recessive.
dominant.s	Logical; if TRUE, the genetic model of the second gene is dominant, otherwise recessive.
mrate	Proportion of missing genotypes, value between 0 and 1. Default value is 0.
hr	Proportion of high risk families, which include at least two affected members, to be sampled from the two stage sampling. This value should be specified when design = "twostage". Default value is 0. Value should lie between 0 and 1.
probandage	Vector of mean and standard deviation for the proband age. Default values are mean of 45 years and standard deviation of 2 years, probandage = c(45, 2).
agemin	Minimum age of disease onset or minimum age. Default is 20 years of age.
agemax	Maximum age of disease onset or maximum age. Default is 100 years of age.

Details

The power of testing $H_0 : \beta_{gene} = 0$ vs. $H_1 : \beta_{gene} =$ effectsize is obtained by the proportion of times the null hypothesis is rejected out of the N.sim simulations.

When interaction = TRUE, the powers of both the main effect of mutated gend and the interaction effect of mutated gene and gender will be computed.

Value

Returns

power	Power of detecting the genetic effect.

LSfam *Ontario Lynch Syndrom families*

Description

Data from 32 Lynch Syndrome families segregating mismatch repair mutations selected from the Ontario Familial Colorectal Cancer Registry that includes 765 individuals, both probands and relatives. The families were ascertained throughout affected and mutation carrier probands.

Usage

```
data("LSfam")
```

Format

A data frame with 765 observations on the following 11 variables.

`famID` Family identification (ID) numbers.

`indID` Individuals ID numbers.

`fatherID` Father ID numbers.

`motherID` Mother ID numbers.

`gender` Gender indicators: 1 for male, 0 for female.

`status` Disease statuses: 1 for affected, 0 for unaffected.

`time` Ages at diagnosis of colorectal cancer for the affected or ages of last follow-up for the unaffected.

`currentage` Current ages in years.

`mgene` MLH1 or MSH2 mutation indicators: 1 for mutated gene carriers, 0 for mutated gene non-carriers, or `NA` if missing.

`proband` Proband indicators: 1 for proband, 0 for non-proband.

`relation` Family members' relationship with the proband. Relation codes:

1	Proband (self)
2	Brother or sister
3	Son or daughter
4	Parent
5	Nephew or niece
6	Spouse
7	Brother or sister in law
8	Paternal grandparent
9	Paternal uncle or aunt
10	Paternal cousin
11	Maternal grandparent
12	Maternal uncle or aunt
13	Maternal cousin
14	Son or daughter in law
15	Grandchild
16	Uncle's or aunt's spouse.

       parms = c(0.05, 2, 1, 3), data = LSfam[!is.na(LSfam$time) & LSfam$time > 18, ],
       method = "mendelian", base.dist = "Weibull", design = "pop+", robust = TRUE)

summary(fit)

penetrance(fit, fixed = c(1, 1), age = c(50, 60, 70), CI = TRUE, MC = 100)
```

`penetrance` *Penetrance function and confidence intervals*

Description

Estimates the cumulative disease risks (penetrances) and confidence intervals at given age(s) based on the fitted penetrance model.

Usage

```
penetrance(fit, fixed, age, CI = TRUE, MC = 100)
```

Arguments

`fit`	An object class of `'penmodel'`, a fitted model by `penmodel` or `penmodelEM` functions.
`fixed`	Vector of fixed values of the covariates used for penetrance calculation.
`age`	Vector of ages used for penetrance calculation.
`CI`	Logical; if `TRUE`, the 95% confidence interval will be obtained using a Monte-Carlo method, otherwise no confidence interval will be provided. Default is `TRUE`.
`MC`	Number of simulated samples used to calculate confidence intervals with a Monte-Carlo method. If `MC=0`, no confidence intervals will be calculated. Default value is 100.

Details

The penetrance function is defined as the probability of developing a disease by age t given fixed values of covariates x,

$$P(T < t|x) = 1 - S(t; x),$$

where t is greater than the minimum age t_0 and $S(t; x)$ is the survival distribution based on a proportional hazards model with a specified baseline hazard distribution.

The proportional hazards model is specified as:

$$h(t|x) = h_0(t) \exp(\beta x),$$

where $h_0(t)$ is the baseline hazards function, x is the vector of covariates and β is the vector of corresponding regression coefficients.

Calculations of standard errors of the penetrance estimates and 95% confidence intervals (CIs) for the penetrance at a given age are based on Monte-Carlo simulations of the estimated penetrance model.

A multivariate normal distribution is assumed for the parameter estimates, and `MC = n` sets of the parameters are generated from the multivariate normal distribution with the parameter estimates and their variance-covariance matrix. For each simulated set, a penetrance estimate is calculated at a given age by substituting the simulated parameters into the penetrance function.

The standard error of the penetrance estimate at a given age is calculated by the standard deviation of penetrance estimates obtained from n simulations.

The 95% CI for the penetrance at a given age is calculated using the 2.5th and 97.5th percentiles of the penetrance estimates obtained from n simulations.

Value

Returns the following values:

`age`	Ages at which the penetrances are calculated.
`penetrance`	Penetrance estimates at given ages.
`lower`	Lower limit of the 95% confidence interval; simulation-based 2.5th percentile of the penetrance estimates.
`upper`	Upper limit of the 95% confidence interval; simulation-based 97.5th percentile of the penetrance estimates.
`se`	Simulation-based standard errors of the penetrance estimates.

```

`penetrance_cmp` *Estimating Penetrances for competing risk models and confidence intervals*

Description

Estimates the cumulative disease risks (penetrances) and confidence intervals for the event of interest in the presence of competing event given fixed values of covariates based on the fitted competing risk model.

Usage

```
penetrance_cmp(fit, event = 1, fixed, age, CI = TRUE, MC = 100)
```

Arguments

`fit`	An object class of `'penmodel_cmp'`, a fitted model by `penmodel_cmp` function.
`event`	Event of interest (either 1 or 2) for penetrance estimation. Default value is 1.
`fixed`	list of vectors of fixed values of the covariates for both events used for penetrance calculation.
`age`	Vector of ages used for penetrance calculation.
`CI`	Logical; if `TRUE`, the 95% confidence interval will be obtained using a Monte-Carlo method, otherwise no confidence interval will be provided. Default is `TRUE`.
`MC`	Number of simulated samples used to calculate confidence intervals with a Monte-Carlo method. If `MC=0`, no confidence intervals will be calculated. Default value is 100.

Details

The cause-specific hazard for event j is specified as:

$$h_j(t|x) = h_{0j}(t)\exp(\beta_j x_j),$$

where $h_{0j}(t)$ is the baseline hazards function for event j, x_j is the vector of covariates associated with event j and β_j is the vector of corresponding regression coefficients, $j = 1, 2$.

The penetrance function for event j in the presence of competing risks based on cause-specific hazards (with no frailties assumed) model is defined as the probability of developing an event of interest by age t given fixed values of covariates x in the following form:

$$P(T < t, d = j|x) = \int_{t_0}^{t} h_j(u|x_j)\exp(-H_1(u|x_1) - H_2(u|x_2))du$$

where t_0 is the minimum age of onset, d is the type of event which takes $(j = 1, 2)$.

The shared frailty competing risks model is:

$$h_j(t|z_j, x_j) = z_j h_{0j}(t) \exp(\beta_j x_j),$$

where z_j is the shared frailty for event j within families whose distribution is specified by `frailty.dist`.

The penetrance function for event j from the shared frailty competing risks model is obtained by integrating over the frailty distribution of $G(z_1, z_2)$,

$$P(T < t, d = j|x) = \int_{t_0}^{t} \int \int h_j(u|x_j, z_j) \exp(-H_1(u|x_1, z_1) - H_2(u|x_2, z_2)) dG(z_1, z_2) du,$$

where t_0 is the minimum age of onset, d is the type of event which takes $(j = 1, 2)$.

See Choi et al. (2021) for more details about the penetrance functions.

Calculations of standard errors of the penetrance estimates and 95% confidence intervals (CIs) for the penetrance at a given age are based on Monte-Carlo simulations of the estimated penetrance model. A multivariate normal distribution is assumed for the parameter estimates, and `MC = n` sets of the parameters are generated from the multivariate normal distribution with the parameter estimates and their variance-covariance matrix. For each simulated set, a penetrance estimate is calculated at a given age by substituting the simulated parameters into the penetrance function.

The standard error of the penetrance estimate at a given age is calculated by the standard deviation of penetrance estimates obtained from n simulations.

The 95% CI for the penetrance at a given age is calculated using the 2.5th and 97.5th percentiles of the penetrance estimates obtained from n simulations.

Value

Returns the following values:

`age`	Ages at which the penetrances are calculated.
`penetrance`	Penetrance estimates at given ages.
`lower`	Lower limit of the 95% confidence interval; simulation-based 2.5th percentile of the penetrance estimates.
`upper`	Upper limit of the 95% confidence interval; simulation-based 97.5th percentile of the penetrance estimates.
`se`	Simulation-based standard errors of the penetrance estimates.

penmodel *Fit a penetrance model*

Description

Fits a penetrance model for family data based on a prospective likelihood with ascertainment correction and provides model parameter estimates.

Usage

```
penmodel(formula, cluster = "famID", gvar = "mgene", parms, cuts = NULL, data,
design = "pop", base.dist = "Weibull", frailty.dist = "none",
agemin = NULL, robust = FALSE)
```

Arguments

formula	A formula expression as for other regression models. The response should be a survival object as returned by the Surv function. See the documentation for Surv, lm and formula for details.
cluster	Name of cluster variable. Default is "famID".
gvar	Name of genetic variable. Default is "mgene".

parms	Vector of initial values for the parameters in the model including baseline parameters and regression coefficients. parms = c(baseparm, coef), where baseparm includes the initial values for baseline parameters used for base.dist, and coef includes the initial values for regression coefficients for the variables specified in formula. If frailty.dist is specified, the initial value of the frailty parameter should be specified parms = c(baseparm, coef, k), where k the initial value for the frailty parameter. See details for the baseline parameters.
cuts	Vector of cut points that define the intervals where the hazard function is constant. The cuts should be specified when base.dist="piecewise" and must be strictly positive and finite. Default is NULL.
data	Data frame generated from simfam or data frame containing variables named in the formula and specific variables: famID, indID, gender, currentage, mgene, time, status and weight with attr(data,"agemin") specified.
design	Study design of the family data. Possible choices are: "pop", "pop+", "cli", "cli+" or "twostage", where "pop" is for the population-based design with affected probands whose mutation status can be either carrier or non-carrier, "pop+" is similar to "pop" but with mutation carrier probands, "cli" is for the clinic-based design that includes affected probands with at least one parent and one sib affected, "cli+" is similar to "cli" but with mutation carrier probands, and "twostage" is for the two-stage design with oversampling of high risks families. Default is "pop".
base.dist	Choice of baseline hazard distributions to fit. Possible choices are: "Weibull", "loglogistic", "Gompertz", "lognormal", "gamma", "logBurr", or "piecewise". Default is "Weibull".
frailty.dist	Choice of frailty distribution. Possible choices are: "gamma", "lognormal", or "none". Default is "none".
agemin	Minimum age of disease onset or minimum age. Default is NULL.
robust	Logical; if TRUE, the robust 'sandwich' standard errors and variance-covariance matrix are provided, otherwise the conventional standard errors and variance-covariance matrix are provided.

Details

When frailty.dist = "none", the following penetrance model is fitted to family data with a specified baseline hazard distribution

$$h(t|x_s, x_g) = h_0(t - t_0)\exp(\beta_s x_s + \beta_g x_g),$$

where $h_0(t)$ is the baseline hazards function specified by base.dist, which depends on the shape and scale parameters, λ and ρ; x_s indicates male (1) and female (0) and x_g indicates carrier (1) or non-carrier (0) of a gene of interest (major gene). Additional covariates can be added to formula in the model.

When frailty.dist is specified as either "gamma" or "lognormal", the follwoing shared frailty model is fitted to family data

$$h(t|X, Z) = h_0(t - t_0)Z\exp(\beta_s x_s + \beta_g x_g),$$

where $h_0(t)$ is the baseline hazard function, t_0 is a minimum age of disease onset, and Z represents a frailty shared within families whose distribution is specified by `frailty.dist`.

Choice of frailty distributions

`frailty.dist = "gamma"` assumes Z follows Gamma(k, $1/k$).

`frailty.dist = "lognormal"` assumes Z follows log-normal distribution with mean 0 and variance $1/k$.

`frailty.dist = "none"` shares no frailties within families and assumes independence among family members.

For family data arising from population- or clinic-based study designs (`design="pop"`, `"pop+"`, `"cli"`, or `"cli+"`), the parameters of the penetrance model are estimated using the ascertainment-corrected prospective likelihood approach (Choi, Kopciuk and Briollais, 2008).

For family data arising from a two-stage study design (`design="twostage"`), model parameters are estimated using the composite likelihood approach (Choi and Briollais, 2011)

Note that the baseline parameters include `lambda` and `rho`, which represent the scale and shape parameters, respectively, and `eta`, additional parameter to specify for `"logBurr"` distribution. For the `"lognormal"` baseline distribution, `lambda` and `rho` represent the location and scale parameters for the normally distributed logarithm, where `lambda` can take any real values and `rho` > 0. For the other baselinse distributions, `lambda` > 0, `rho` > 0, and `eta` > 0. When a piecewise constant distribution is specified for the baseline hazards, `base.dist="piecewise"`, `baseparm` should specify the initial interval-constant values, one more than the cut points specified by`cuts`.

Transformed baseline parameters are used for estimation; log transformation is applied to both scale and shape parameters (λ, ρ) for `"Weibull"`, `"loglogistic"`, `"Gompertz"` and `"gamma"` baselines, to (λ, ρ, η) for `"logBurr"` and to the piecewise constant parameters for a `piecewise` baseline hazard. For `"lognormal"` baseline distribution, the log transformation is applied only to ρ, not to λ, which represents the location parameter for the normally distributed logarithm.

Calculations of penetrance estimates and their standard errors and 95% confidence intervals at given ages can be obtained by `penetrance` function via Monte-Carlo simulations of the estimated penetrance model.

Value

Returns an object of class `'penmodel'`, including the following elements:

`estimates`	Parameter estimates of transformed baseline parameters and regression coefficients.
`varcov`	Variance-covariance matrix of parameter estimates obtained from the inverse of Hessian matrix.
`varcov.robust`	Robust 'sandwich' variance-covariance matrix of parameter estimates when `robust=TRUE`.
`se`	Standard errors of parameter estimates obtained from the inverse of Hessian matrix.
`se.robust`	Robust 'sandwich' standard errors of parameter estimates when `robust=TRUE`.
`logLik`	Loglikelihood value for the fitted penetrance model.
`AIC`	Akaike information criterion (AIC) value of the model; AIC = 2*k - 2*logLik, where k is the number of parameters used in the model.

penmodelEM *EM algorithm for estimating the penetrance model with missing genotypes*

Description

Fits a penetrance model for family data with missing genotypes via the EM algorithm and provides model parameter estimates.

Usage

```
penmodelEM(formula, cluster = "famID", gvar = "mgene", parms, cuts = NULL, data,
design = "pop", base.dist = "Weibull", agemin = NULL, robust = FALSE, method = "data",
mode = "dominant", q = 0.02)
```

Arguments

formula	A formula expression as for other regression models. The response should be a survival object as returned by the Surv function. See the documentation for Surv, lm and formula for details.
cluster	Name of cluster variable. Default is "famID".
gvar	Name of genetic variable. Default is "mgene".
parms	Vector of initial values for the parameters in the model including baseline parameters and regression coefficients. parms = c(baseparm, coef), where baseparm includes the initial values for baseline parameters used for base.dist, and coef includes the initial values for regression coefficients for the variables specified in formula. See details for the baseline parameters.
cuts	Vector of cuts that define the intervals where the hazard function is constant. The cuts should be specified base.dist="piecewise" and must be strictly positive and finite. Default is NULL.
data	Data frame generated from simfam or data frame containing specific variables: famID, indID, gender, currentage, mgene, time, status and weight with attr(data,"agemin") specified.
design	Study design of the family data. Possible choices are: "pop", "pop+", "cli", "cli+" or "twostage", where "pop" is for the population-based design with affected probands whose mutation status can be either carrier or non-carrier, "pop+" is similar to "pop" but with mutation carrier probands, "cli" is for the clinic-based design that includes affected probands with at least one parent and one sib affected, "cli+" is similar to "cli" but with mutation carrier probands, and "twostage" is for the two-stage design with oversampling of high risks families. Default is "pop".
base.dist	Choice of baseline hazard distributions to fit. Possible choices are: "Weibull", "loglogistic", "Gompertz", "lognormal", "gamma", "logBurr", or "piecewise". Default is "Weibull".
agemin	Minimum age of disease onset or minimum age. Default is NULL.
robust	Logical; if TRUE, the robust 'sandwich' standard errors and variance-covariance matrix are provided, otherwise the conventional standard errors and variance-covariance matrix are provided.
method	Choice of methods for calculating the carrier probabilities for individuals with missing mutation status. Possible choices are "data" for empirical calculation of the carrier probabilities based on the observed carriers' statuses in the entire sample, specific to generation and proband's mutation status or "mendelian" for calculating carrier probabilities based on Mendelian transmission probabilities with the given allele frequency and mutation statuses observed in the family. Default is "data".

If `method = "mendelian"`, specify both `mode` of the inheritance and the allele frequency `q`.

`mode` Choice of modes of inheritance for calculating carrier probabilies for individuals with missing mutation status. Possible choices are `"dominant"` for dominant model or `"recessive"` for recessive model. Default is `"dominant"`.

`q` Frequency of the disease causing allele used for calculating carrier pobabilities. The value should be between 0 and 1. If `NULL`, the estimated allele frequency from data will be used. Default value is `0.02`.

Details

The expectation and maximization (EM) algorithm is applied for making inference about the missing genotypes. In the expectation step, for individuals with unknown carrier status, we first compute their carrier probabilities given their family's observed phenotype and genotype information based on current estimates of parameters θ as follows,

$$w_{fi} = P(X_{fi} = 1 | Y_{fi}, X_f^o),$$

where X_{fi} represents the mutation carrier status and Y_{fi} represents the phenotype in terms of age at onset t_{fi} and disease status δ_{fi} for individual $i, i = 1, \ldots, n_f$, in family $f, f = 1, ..., n$, and X_f^o represents the observed genotypes in family f.

Then, we obtain the conditional expectation of the log-likelihood function (ℓ) of the complete data given the observed data as a weighted log-likelihood, which has the form

$$E_\theta[\ell(\theta|Y, X^o)] = \sum_f^n \sum_i^{n_f} \ell_{fi}(\theta|X_{fi} = 1) w_{fi} + \ell_{fi}(\theta|X_{fi} = 0)(1 - w_{fi}).$$

In the maximization step, the updated parameter estimates are obtained by maximizing the weighted log likelihood computed in the E-step. These expectation and maximization steps iterate until convergence to obtain the maximum likelihood estimates. See more details in Choi and Briollais (2011) or Choi et al. (2014).

Note that the baseline parameters include `lambda` and `rho`, which represent the scale and shape parameters, respectively, and `eta`, additional parameter to specify for `"logBurr"` distribution. For the `"lognormal"` baseline distribution, `lambda` and `rho` represent the location and scale parameters for the normally distributed logarithm, where `lambda` can take any real values and `rho` > 0. For the other baselinse distributions, `lambda` > 0, `rho` > 0, and `eta` > 0. When a piecewise constant distribution is specified for the baseline hazards, `base.dist="piecewise"`, `baseparm` should specify the initial interval-constant values, one more than the cut points specified by`cuts`.

Transformed baseline parameters are used for estimation; log transformation is applied to both scale and shape parameters (λ, ρ) for `"Weibull"`, `"loglogistic"`, `"Gompertz"` and `"gamma"` baselines, to (λ, ρ, η) for `"logBurr"` and to the piecewise constant parameters for a `piecewise` baseline hazard. For `"lognormal"` baseline distribution, the log transformation is applied only to ρ, not to λ, which represents the location parameter for the normally distributed logarithm.

Calculations of penetrance estimates and their standard errors and 95% confidence intervals at given ages can be obtained by `penetrance` function via Monte-Carlo simulations of the estimated penetrance model.

Value

Returns an object of class 'penmodel', including the following elements:

estimates	Parameter estimates of transformed baseline parameters and regression coefficients.
varcov	Variance-covariance matrix of parameter estimates obtained from the inverse of Hessian matrix.
varcov.robust	Robust 'sandwich' variance-covariance matrix of parameter estimates when robust=TRUE.
se	Standard errors of parameter estimates obtained from the inverse of Hessian matrix.
se.robust	Robust 'sandwich' standard errors of parameter estimates when robust=TRUE.
logLik	Loglikelihood value for the fitted penetrance model.
AIC	Akaike information criterion (AIC) value of the model; AIC = 2*k - 2*logLik, where k is the number of parameters used in the model.

penmodel_cmp *Fit a penetrance model for competing risks data*

Description

Fits a competing risks model for family data with ascertainment correction and provides model parameter estimates.

Usage

```
penmodel_cmp(formula1, formula2, cluster = "famID", gvar = "mgene",
parms, cuts = NULL, data,  design = "pop", base.dist = "Weibull",
frailty.dist = "none", agemin = NULL, robust = FALSE)
```

Arguments

formula1	A formula expression for event 1 as for other regression models. The response should be a survival object as returned by the Surv function. See the documentation for Surv, lm and formula for details.
formula2	A formula expression for event 2 as for other regression models. The response should be a survival object as returned by the Surv function. See the documentation for Surv, lm and formula for details.
cluster	Name of cluster variable. Default is "famID".
gvar	Name of genetic variable. Default is "mgene".
parms	list of Vectors of initial values for the parameters in each model including baseline parameters and regression coefficients and frailty parameters. parms = list(c(baseparm1, coef1), c(baseparms2, coef2), c(k1, k2), where baseparm1 and baseparm2 include the initial values for baseline parameters used for each base.dist; coef1 and coef2 include the initial values for regression coefficients for the variables specified in formula1 and formula2, respectively, and c(k1, k2) are the initial values for frailty parameters used for the specified frailty.distribution. See Details for more details.

cuts	Vector of cut points that define the intervals when base.dist="piecewise" is specified and must be strictly positive and finite and greater than agemin. Default is NULL.
data	Data frame generated from simfam or data frame containing variables named in the formula and specific variables: famID, indID, gender, currentage, mgene, time, status and weight with attr(data,"agemin") specified.
design	Study design of the family data. Possible choices are: "pop" and "pop+", where "pop" is for the population-based design with affected probands whose mutation status can be either carrier or non-carrier, "pop+" is similar to "pop" but with mutation carrier probands. Default is "pop".
base.dist	Vector of two baseline hazard distributions to be fitted for competing events. Possible choices for each event are: "Weibull", "loglogistic", "Gompertz", "lognormal", "gamma", "logBurr", or "piecewise". If only one distribution is specified, the same distribution will be assumed for both events. A vector of two distributions should be specified if different baseline distributions are assumed for different events. Default is c("Weibull", "Weibull").
frailty.dist	Choice of frailty distribution to fit a shared frailty model for competing events. Possible choices are: "gamma" for independent gamma, "lognormal" for independent log-normal, "cgamma" for correlated gamma, "clognormal" for correlated log-normal distributions, or "none" can be chosen to ignoring frailties in the model assuming no residual familial correlation given covariates. Default is "gamma").
agemin	Minimum age of disease onset or minimum age. Default is NULL.
robust	Logical; if TRUE, the robust 'sandwich' standard errors and variance-covariance matrix are provided, otherwise the conventional standard errors and variance-covariance matrix are provided.

Details

The shared frailty comepting risks model is fitted to family data with specified baseline hazard distributions and frailty distribution

Event 1:

$$h(t|X, Z_1) = h_{01}(t - t_0)Z \exp(\beta_{s1}x_s + \beta_{g1}x_g),$$

Event 2:

$$h(t|X, Z_1) = h_{02}(t - t_0)Z \exp(\beta_{s2}x_s + \beta_{g2}x_g),$$

where $h_{01}(t)$ and $h_{02}(t)$ are the baseline hazard functions for event 1 and event 2, respectively, which can be specified by base.dist. t_0 is a minimum age of disease onset, Z_1 and Z_2 are frailties shared within families for each event and follow either a gamma, log-normal, correlateg gamma, or correlated log-normal distributions, which can be specified by frailty.dist. x_s and x_g indicate male (1) or female (0) and carrier (1) or non-carrier (0) of a main gene of interest, respectively. Additional covariates can be added to formula1 for event 1 and formula2 for event 2 in the model.

Choice of frailty distributions for competing risk models

`frailty.dist = "gamma"` shares the frailties within families generated from a gamma distribution independently for each competing event, where Z_j follows Gamma(k_j, $1/k_j$).

`frailty.dist = "lognormal"` shares the frailties within families generated from a log-normal distribution independently for each competing event, where Z_j follows log-normal distribution with mean 0 and variance $1/k_j$.

`frailty.dist = "cgamma"` shares the frailties within families generated from a correlated gamma distribution to allow the frailties between two events to be correlated, where the correlated gamma frailties (Z_1, Z_2) are generated with three independent gamma frailties (Y_0, Y_1, Y_2) as follows:

$Z_1 = (k_0/(k_0 + k_1)Y_0 + Y_1$;

$Z_2 = (k_0/(k_0 + k_2)Y_0 + Y_2$,

where Y_0 from Gamma(k_0, $1/k_0$), Y_1 from Gamma(k_1, $1/(k_0 + k_1)$), Y_2 from Gamma(k_2, $1/(k_0 + k_2)$).

`frailty.dist = "clognormal"` shares the frailties within families generated from a correlated log-normal distribution where $log(Z_j)$ follows a normal distribution with mean 0, variance $1/k_j$ and correlation between two events k_0.

`depend` should specify the values of related frailty parameters: `c(k1, k2)` with `frailty.dist = "gamma"` or `frailty.dist = "lognormal"`; `c(k1, k2, k0)` for `frailty.dist = "cgamma"` or `frailty.dist = "clognormal"`.

More details about the competing risks model for family data arising from population-based study designs (`design="pop"`, `"pop+"` and their inference procedure based on the ascertainment-corrected likelihood approach can be found in Choi et al., 2021.

Note that the baseline parameters include `lambda` and `rho`, which represent the scale and shape parameters, respectively, and `eta`, additional parameter to specify for `"logBurr"` distribution. For the `"lognormal"` baseline distribution, `lambda` and `rho` represent the location and scale parameters for the normally distributed logarithm, where `lambda` can take any real values and `rho` > 0. For the other baselinse distributions, `lambda` > 0, `rho` > 0, and `eta` > 0. When a piecewise constant distribution is specified for the baseline hazards, `base.dist="piecewise"`, `baseparm` should specify the initial interval-constant values, one more than the cut points specified by`cuts`.

Transformed baseline parameters are used for estimation; log transformation is applied to both scale and shape parameters (λ, ρ) for `"Weibull"`, `"loglogistic"`, `"Gompertz"` and `"gamma"` baselines, to (λ, ρ, η) for `"logBurr"` and to the piecewise constant parameters for a `piecewise` baseline hazard. For `"lognormal"` baseline distribution, the log transformation is applied only to ρ, not to λ, which represents the location parameter for the normally distributed logarithm.

Calculations of penetrance estimates and their standard errors and 95% confidence intervals at given ages can be obtained by `penetrance` function via Monte-Carlo simulations of the estimated penetrance model.

Value

Returns an object of class `'penmodel_cmp'`, including the following elements:

`estimates`	Parameter estimates of transformed baseline parameters and regression coefficients.
`varcov`	Variance-covariance matrix of parameter estimates obtained from the inverse of Hessian matrix.

varcov.robust	Robust 'sandwich' variance-covariance matrix of parameter estimates when robust=TRUE.
se	Standard errors of parameter estimates obtained from the inverse of Hessian matrix.
se.robust	Robust 'sandwich' standard errors of parameter estimates when robust=TRUE.
logLik	Loglikelihood value for the fitted penetrance model.
AIC	Akaike information criterion (AIC) value of the model; AIC = 2*k - 2*logLik, where k is the number of parameters used in the model.

`penplot` *Plot penetrance functions*

Description

Plots the penetrance functions given the values of baseline parameters and regression coefficients and choices of baseline and frailty distributions.

Usage

```
penplot(base.parms, vbeta, cuts = NULL, variation = "none", base.dist = "Weibull",
frailty.dist = NULL, depend = 1, agemin = 20, agemax = 80, print = TRUE,
col = c("blue","red","blue","red"),  lty = c(1, 1, 2, 2), add.legend = TRUE,
add.title = TRUE, x = "topleft", y = NULL, xlab = "Age at onset", ylab = "Penetrance",
ylim = NULL, main = NULL, ...)
```

Arguments

`base.parms`	Vector of parameter values for the specified baseline hazard function: `base.parms = c(lambda, rho)` should be specified for `base.dist = "Weibull"`, `"loglogistic"`, `"Gompertz"`, `"gamma"`, and `"lognormal"`, `c(lambda, rho, eta)` for `base.dist = "logBurr"`, or interval constant hazard values for the intervals produced by `cuts` for `base.dist = "piecewise"`.
`vbeta`	Vector of regression coefficients for gender and majorgene, `vbeta = c(beta.s, beta.g)`. If `variation = "secondgene"`, regression coefficients for gender, major gene and second gene, `vbeta = c(beta.s, beta.g1, beta.g2)`, should be specified.
`cuts`	Vector of cut points defining the intervals where the hazard function is constant. The `cuts` should be specified when `base.dist = "piecewise"` and must be strictly positive and finite. Default is `NULL`.

variation	Source of residual familial correlation. Possible choices are: "frailty" for frailty shared within families, "secondgene" for second gene variation, or "none" for no residual familial correlation. Default is "none".
base.dist	Choice of baseline hazard distribution. Possible choices are: "Weibull", "loglogistic", "Gompertz", "lognormal", "gamma", or "piecewise". Default is "Weibull".
frailty.dist	Choice of frailty distribution. Possible choices are "gamma" for gamma distribution or "lognormal" for log normal distributions when variation = "frailty". Default is NULL.
depend	Variance of the frailty distribution. Dependence within families increases with depend value. Default value is 1.
agemin	Minimum age of disease onset. Default is 20 years of age.
agemax	Maximum age of disease onset. Default is 80 years of age.
print	Logical; if TRUE, prints the penetrance values by age 70 obtained from the assumed model for male carriers, female carriers, male noncarrers, and female noncarriers. Default is TRUE.
col	Colors of lines for male carriers, female carriers, male noncarrers, and female noncarriers. Default is c("blue", "red", "blue", "red").
lty	Types of lines for male carriers, female carriers, male noncarriers, and female noncarriers. Default is c(1, 1, 2, 2).
add.legend	Logical; if TRUE, displays legend in the plot. Default is TRUE.
add.title	Logical; if TRUE, displays title in the plot. Default is TRUE.
x, y	Position of legend; see legend. Defaults are x = "topleft", y = NULL.
xlab	Title for the x-axis. Default is "Age at onset".
ylab	Title for the y-axis. Default is "Penetrance".
ylim	Limits of the y-axis. Default is NULL. If NULL, ylim will be automatically determined.
main	Main title of the plot. Default is NULL. If NULL, the title will be automatically created.
...	Other parameters to be passed through to plotting functions.

Details

Proportional hazard models

The penetrance model conditional on the covariates $X = (x_s, x_g)$ is assumed to have the following hazard function:

$$h(t|X) = h_0(t - t_0)\exp(\beta_s x_s + \beta_g x_g),$$

where $h_0(t)$ is the baseline hazard function, t_0 is a minimum age of disease onset, x_s and x_g indicate male (1) or female (0) and carrier (1) or non-carrier (0) of a main gene of interest, respectively.

The penetrance function for the penetrance model has the form,

$$1 - \exp\left\{-H_0(t - t_0)\exp(\beta_s x_s + \beta_g x_g)\right\},$$

where $H_0(t)$ is the cumulative baseline hazard function.

Shared frailty models

The penetrance model conditional on the frailty Z and covariates $X = (x_s, x_g)$ is assumed to have the following hazard function:

$$h(t|X, Z) = h_0(t - t_0)Z \exp(\beta_s x_s + \beta_g x_g),$$

where $h_0(t)$ is the baseline hazard function, t_0 is a minimum age of disease onset, x_s and x_g indicate male (1) or female (0) and carrier (1) or non-carrier (0) of a main gene of interest, respectively.

For example, when using a Weibull distribution for baseline hazard and a gamma distribution for frailty, the penetrance function has the form

$$1 - \left\{1 + \frac{\lambda^\rho (t - t_0)^\rho \exp(\beta_s x_s + \beta_g x_g)}{\kappa}\right\}^{-\kappa}.$$

Two-gene models

The penetrance curve for the two-gene model is generated by

$$1 - \exp\left\{-H_0(t - t_0)\exp(\beta_s x_s + \beta_{g1} x_{g1} + \beta_{g2} x_{g2})\right\},$$

where $H_0(t)$ is the cumulative baseline hazard function, x_{g1} indicates carrior (1) or non-carrior (0) of a major gene and x_{g2} indicates carrior (1) or non-carrior (0) of a second gene. When plotting with the two-gene model, the plot will generate separate curves for mutation carriers and noncarriers, and separate curves for the second gene carriers and noncarriers.

Value

Displays plots of the penetrance functions and returns the following values:

`pen70`	Penetrance estimates by age 70 specific to gender and mutation-status subgroups.
`x.age`	Vector of ages of onset ranging from `agemin` to `agemax` years
`pen`	Penetrance estimates computed at each age of `x.age`; if `variation` = `"none"` or `"frailty"`, it includes subgroups specific to gender and mutation status for major gene. If `variation` = `"secondgene"`, it includes subgroups specific to gender and both mutation statuses for major gene and second gene.

```

penplot_cmp *Plot penetrance functions from competing risk models*

Description

Plots the penetrance functions from competing risk models given the values of baseline parameters and regression coefficients and choices of baseline and frailty distributions.

Usage

```
penplot_cmp(event, base.parms, vbeta, cuts = NULL, variation = "none",
          base.dist = "Weibull", frailty.dist = NULL, depend = c(1, 1),
          agemin = 20, agemax = 80, print = TRUE,
          col = c("blue","red","blue","red"),  lty = c(1, 1, 2, 2),
          add.legend = TRUE, add.title = TRUE, x = "topleft",
          y = NULL, xlab = "Age at onset", ylab = "Penetrance",
          ylim = NULL, main = NULL, ...)
```

Arguments

event	Event of interest for penetrance function: either 1 or 2. Default is 1.
base.parms	List of vectors of parameter values for the specified baseline hazard functions for both events. For example, base.parms = list(c(lambda1, rho1), c(lambda2, rho2)) should be specified when base.dist = c("Weibull", "Weibull").
vbeta	List of vectors of regression coefficients for gender and majorgene, vbeta = list(c(beta1.s, beta1.g), c(beta2.s, beta2.g)) for both events. If variation = "secondgene", regression coefficients for gender, major gene and second gene, vbeta = list(c(beta1.s, beta1.g1, beta1.g2), c(beta2.s, beta2.g1, beta2.g2)), should be specified for each event.
cuts	Vector of cut points defining the intervals when base.dist = "piecewise" is specified and must be strictly positive and finite and greater than agemin. Default is NULL.
variation	Source of residual familial correlation. Possible choices are: "frailty" for frailty shared within families, "secondgene" for second gene variation, or "none" for no residual familial correlation. Default is "none".
base.dist	Vector of two baseline hazard distributions chosen for competing events. Possible choices are: "Weibull", "loglogistic", "Gompertz", "lognormal", "gamma", or "piecewise".If only one distribution is specified, the same distribution will be assumed for both events. A vector of two distributions should be specified if different baseline distributions are assumed for different events. Default is c("Weibull", "Weibull").
frailty.dist	Choice of frailty distribution. Possible choices are "gamma" for independent gamma, "lognormal" for independent log-normal, "cgamma" for correlated gamma, "clognormal" for correlated log-normal distribution when variation = "frailty" or "none" or NULL when no frailty distribution is assumed. Default is NULL.

depend	Vector of frailty parameter values assumed for specified frailty distribution. They corresponds inverse of variance of the frailty distribution. Dependence within families decreases with depend value. Default value is c(1,1).
agemin	Minimum age of disease onset. Default is 20 years of age.
agemax	Maximum age of disease onset. Default is 80 years of age.
print	Logical; if TRUE, prints the penetrance values by age 70 obtained from the assumed model for male carriers, female carriers, male noncarrers, and female noncarriers. Default is TRUE.
col	Colors of lines for male carriers, female carriers, male noncarrers, and female noncarriers. Default is c("blue", "red", "blue", "red").
lty	Types of lines for male carriers, female carriers, male noncarriers, and female noncarriers. Default is c(1, 1, 2, 2).
add.legend	Logical; if TRUE, displays legend in the plot. Default is TRUE.
add.title	Logical; if TRUE, displays title in the plot. Default is TRUE.
x, y	Position of legend; see legend. Defaults are x = "topleft", y = NULL.
xlab	Title for the x-axis. Default is "Age at Onset".
ylab	Title for the y-axis. Default is "Penetrance".
ylim	Limits of the y-axis. Default is NULL. If NULL, ylim will be automatically determined.
main	Main title of the plot. Default is NULL. If NULL, the title will be automatically created.
...	Other parameters to be passed through to plotting functions.

Details

Cause-specific proportional hazard models The penetrance models for competing events conditional on the covariates $X = (x_s, x_g)$ are assumed to have the following hazard functions for event $j = 1, 2$:

$$h_j(t|X) = h_{0j}(t - t_0) \exp(\beta_{js} x_s + \beta_{jg} x_g),$$

where $h_{0j}(t)$ is the baseline hazard function for event j, $j = 1, 2$, t_0 is a minimum age of disease onset, x_s and x_g indicate male (1) or female (0) and carrier (1) or non-carrier (0) of a major gene of interest, respectively.

The penetrance function for the penetrance model has the form,

$$1 - \exp\left\{-H_0(t - t_0) \exp(\beta_s x_s + \beta_g x_g)\right\},$$

where $H_0(t)$ is the cumulative baseline hazard function.

Shared frailty models

The penetrance model conditional on the frailty Z and covariates $X = (x_s, x_g)$ is assumed to have the following hazard function:

$$h(t|X, Z) = h_0(t - t_0) Z \exp(\beta_s x_s + \beta_g x_g),$$

where $h_0(t)$ is the baseline hazard function, t_0 is a minimum age of disease onset, x_s and x_g indicate male (1) or female (0) and carrier (1) or non-carrier (0) of a main gene of interest, respectively.

For example, when using a Weibull distribution for baseline hazard and a gamma distribution for frailty, the penetrance function has the form

$$1 - \left\{1 + \frac{\lambda^\rho (t - t_0)^\rho \exp(\beta_s x_s + \beta_g x_g)}{\kappa}\right\}^{-\kappa}.$$

Two-gene models

The penetrance curve for the two-gene model is generated by

$$1 - \exp\left\{-H_0(t - t_0)\exp(\beta_s x_s + \beta_{g1} x_{g1} + \beta_{g2} x_{g2})\right\},$$

where $H_0(t)$ is the cumulative baseline hazard function, x_{g1} indicates carrior (1) or non-carrior (0) of a major gene and x_{g2} indicates carrior (1) or non-carrior (0) of a second gene. When plotting with the two-gene model, the plot will generate separate curves for mutation carriers and noncarriers, and separate curves for the second gene carriers and noncarriers.

Value

Displays plots of the penetrance functions and returns the following values:

`pen70`	Penetrance estimates by age 70 specific to gender and mutation-status subgroups.
`x.age`	Vector of ages of onset ranging from `agemin` to `agemax` years
`pen`	Penetrance estimates computed at each age of `x.age`; if `variation = "none"` or `"frailty"`, it includes subgroups specific to gender and mutation status for major gene. If `variation = "secondgene"`, it includes subgroups specific to gender and both mutation statuses for major gene and second gene.

`plot.penmodel` *Plot method for* `penmodel`

Description

Plots penetrance curves estimated from the fitted penetrance model and overlays non-parametric penetrance curves estimated from the data without proabands.

Usage

```
## S3 method for class 'penmodel'
plot(x, agemax = 80, print = TRUE, mark.time = FALSE, conf.int = FALSE,
add.KM = TRUE, MC = 100, col = c("blue", "red", "blue", "red"), lty = c(1, 1, 2, 2),
add.legend = TRUE, add.title = TRUE, xpos = "topleft", ypos = NULL,
xlab = "Age at onset", ylab = "Penetrance", ylim = NULL, main = NULL,  ...)
```

Arguments

`x`	An object class of `'penmodel'`, a fitted model by `penmodel` or `penmodelEM` functions.
`agemax`	Maximum age of disease onset or maximum age. Default is 80 years of age.
`print`	Logical; if `TRUE`, displays parameter estimates and penetrance estimates by age 70.
`mark.time`	Logical; if `TRUE`, curves are marked at each censoring time, otherwise, no labeling is done.
`conf.int`	Logical; if `TRUE`, displays 95% confidence intervals for both parametric and non-parametric penetrance estimates for each subgroup and returns their `lower` and `upper` limits.
`add.KM`	Logical; if `TRUE`, displays Kaplan-Meier curves from data.

MC	Number of simulated samples used to calculate confidence intervals with a Monte-Carlo method. If MC = 0, no confidence intervals will be calculated. Default value is 100.
col	Colors of lines for male carriers, female carriers, male noncarrers, and female noncarriers. Default is c("blue", "red", "blue", "red").
lty	Types of lines for male carriers, female carriers, male noncarriers, and female noncarriers. Default is c(1, 1, 2, 2).
add.legend	Logical; if TRUE, displays a legend in the plot.
add.title	Logical; if TRUE, displays a title in the plot.
xpos, ypos	Position of legend; see legend. Defaults are xpos = "topleft", ypos = NULL.
xlab	Title for the x-axis. Default is "Age at onset".
ylab	Title for the y-axis. Default is "Penetrance".
ylim	Limits for the y-axis. Default is NULL. If NULL, ylim will be automatically determined.
main	Main title of the plot. Default is NULL. If NULL, the title will be automatically created.
...	Other parameters to be passed through to plotting functions.

Details

The 95% confidence intervals for the parametric penetrance curves are obtained based on simulations of the parameters, assuming a multivariate normal distribution for the estimated parameters with their variance-covariance matrix. See penetrance for more details.

Value

Returns the following summary values:

coefficients	Parameter estimates of transformed baseline parameters (λ, ρ) and regression coefficients for gender and mutation status (β_s, β_g).
pen70	Penetrance estimates by age 70, specific to gender and mutation-status subgroups.
x.age	Vector of ages of onsest ranging from agemin to agemax years
pen	Penetrance estimates at each age in x.age, specific to gender and mutation-status subgroups.
lower	Lower limits of 95% confidence interval estimates for penetrance at each age in x.age, specific to gender and mutation status subgroups.
upper	Upper limits of 95% confidence interval estimates for penetrance at each age in x.age, specific to gender and mutation status subgroups.

plot.penmodel_cmp *Plot method for* penmodel_cmp

Description

Plots penetrance curves for each event estimated from the fitted competing risks model and overlays non-parametric cumulative incidence curves estimated from the data without proabands.

Usage

```
## S3 method for class 'penmodel_cmp'
plot(x, agemax = 80, print = TRUE, conf.int = FALSE,
add.CIF = TRUE, MC = 100, col = c("blue", "red", "blue", "red"), lty = c(1, 1, 2, 2),
xlab = "Age at onset", ylab = "Penetrance", ylim = NULL,  ...)
```

Arguments

x	An object class of 'penmodel', a fitted model by penmodel or penmodelEM functions.
agemax	Maximum age of disease onset or maximum age. Default is 80 years of age.
print	Logical; if TRUE, displays parameter estimates and penetrance estimates by age 70.
conf.int	Logical; if TRUE, displays 95% confidence intervals for both parametric and non-parametric penetrance estimates for each subgroup and returns their lower and upper limits.

add.CIF	Logical; if TRUE, displays cumulative incidence curves from competing event data.
MC	Number of simulated samples used to calculate confidence intervals with a Monte-Carlo method. If MC = 0, no confidence intervals will be calculated. Default value is 100.
col	Colors of lines for male carriers, female carriers, male noncarrers, and female noncarriers. Default is c("blue", "red", "blue", "red").
lty	Types of lines for male carriers, female carriers, male noncarriers, and female noncarriers. Default is c(1, 1, 2, 2).
xlab	Title for the x-axis. Default is "Age at onset".
ylab	Title for the y-axis. Default is "Penetrance".
ylim	Limits for the y-axis. Default is NULL. If NULL, ylim will be automatically determined.
...	Other parameters to be passed through to plotting functions.

Details

The 95% confidence intervals for the parametric penetrance curves are obtained based on simulations of the parameters, assuming a multivariate normal distribution for the estimated parameters with their variance-covariance matrix. See penetrance_cmp for more details.

Value

Returns the following summary values:

coefficients	Parameter estimates from the competing risks model.
pen70	Penetrance estimates by age 70, specific to gender and mutation-status subgroups.
age	Vector of ages of onsest ranging from agemin to agemax years
pen1	Penetrance estimates for event 1 at each age in age, specific to gender and mutation-status subgroups.
pen2	Penetrance estimates for event 2 at each age in age, specific to gender and mutation-status subgroups.
lower1	Lower limits of 95% confidence interval estimates for penetrance for event 1 at each age in age, specific to gender and mutation status subgroups.
upper1	Upper limits of 95% confidence interval estimates for penetrance for event 1 at each age in x.age, specific to gender and mutation status subgroups.
lower2	Lower limits of 95% confidence interval estimates for penetrance for event 2 at each age in age, specific to gender and mutation status subgroups.
upper2	Upper limits of 95% confidence interval estimates for penetrance for event 2 at each age in x.age, specific to gender and mutation status subgroups.

plot.simfam *Plot method for* simfam *or Plot pedigrees*

Description

Provides pedigree plots for specified families generated from simfam function with option to save plots into a pdf file.

Usage

```
## S3 method for class 'simfam'
plot(x, famid, pdf = FALSE, file = NULL, ...)
```

Arguments

x	An object of class 'simfam' created by simfam function or a data frame that has class attributes c("simfam", "data.frame").
famid	List of family IDs to plot. Default is the first family in given data set.

pdf	Logical; if TRUE, pedigree plots are saved in a pdf file. If FALSE, plot pedigrees on current plotting device. Default is FALSE.
file	File name to save the pedigree plots; Default file name is "pedigreeplot.pdf".
...	Additional arguments passed on to the plot function.

Details

Argument x can be a data frame that contains famID, indID, fatherID, motherID, gender (1 for male, 0 for female), status (1 for affected, 0 for non-affected), mgene (1 for mutation carrier, 0 for non-carrier, NA for missing), and proband (1 for proband, 0 for non-proband) and should have class attributes class(x) <- c("simfam", "data.frame").

Optionally, the data frame can contain a column named carrp.geno or carrp.pheno to replace missing values in mgene with their carrier probabilities.

Value

Returns pedigree plots for specified families created by simfam function or for the data frame provided along with the affection and carrier mutation statuses of family members. Probands from each pedigree are indicated using red color.

When object inlcudes carrp.geno and/or carrp.pheno generated by carrierprob function, the plot function displays the carrier probabilities for those with missing carrier status.

---

plot.simfam2 *Plot method for* simfam2 *or Plot pedigrees*

Description

Provides pedigree plots for specified families generated from simfam2 function with option to save plots into a pdf file.

Usage

```
## S3 method for class 'simfam2'
plot(x, famid, pdf = FALSE, file = NULL, ...)
```

Arguments

x	An object of class 'simfam2' created by simfam2 function or a data frame that has class attributes c("simfam2", "data.frame").
famid	List of family IDs to plot. Default is the first family in given data set.
pdf	Logical; if TRUE, pedigree plots are saved in a pdf file. If FALSE, plot pedigrees on current plotting device. Default is FALSE.
file	File name to save the pedigree plots; Default file name is "pedigreeplot.pdf".
...	Additional arguments passed on to the plot function.

Details

Argument x can be a data frame that contains famID, indID, fatherID, motherID, gender (1 for male, 0 for female), status (1 for affected, 0 for non-affected), mgene (1 for mutation carrier, 0 for non-carrier, NA for missing), and proband (1 for proband, 0 for non-proband) and should have class attributes class(x) <- c("simfam", "data.frame").

Optionally, the data frame can contain a column named carrp.geno or carrp.pheno to replace missing values in mgene with their carrier probabilities.

Value

Returns pedigree plots for specified families created by simfam2 function or for the data frame provided along with the affection and carrier mutation statuses of family members. Probands from each pedigree are indicated using red color.

When object inlcudes carrp.geno and/or carrp.pheno generated by carrierprob function, the plot function displays the carrier probabilities for those with missing carrier status.

        base.dist = "Weibull", base.parms = c(0.016, 3),
```

```
        var_names = c("gender", "mgene"), vbeta = c(1,1),
        agemin=20)

plot(fam2, famid = c(1:2))
```

`plot.simfam_cmp` *Plot method for* `simfam_cmp` *or Plot pedigrees*

Description

Provides pedigree plots for specified families generated from `simfam_cmp` function with option to save plots into a pdf file.

Usage

```
## S3 method for class 'simfam_cmp'
plot(x, famid, pdf = FALSE, file = NULL, ...)
```

Arguments

`x`	An object of class `'simfam'` created by `simfam` function or a data frame that has class attributes `c("simfam", "data.frame")`.
`famid`	List of family IDs to plot. Default is the first family in given data set.
`pdf`	Logical; if `TRUE`, pedigree plots are saved in a pdf file. If `FALSE`, plot pedigrees on current plotting device. Default is `FALSE`.
`file`	File name to save the pedigree plots; Default file name is `"pedigreeplot.pdf"`.
`...`	Additional arguments passed on to the plot function.

Details

Argument `x` can be a data frame that contains `famID`, `indID`, `fatherID`, `motherID`, `gender` (1 for male, 0 for female), `status` (1 for affected by event 1, 2 for affected by event 2, 0 for non-affected), `mgene` (1 for mutation carrier, 0 for non-carrier, `NA` for missing), and `proband` (1 for proband, 0 for non-proband) and should have class attributes `class(x) <- c("simfam", "data.frame")`.

Optionally, the data frame can contain a column named `carrp.geno` or `carrp.pheno` to replace missing values in `mgene` with their carrier probabilities.

Value

Returns pedigree plots for specified families created by `simfam_cmp` function or for the data frame provided along with the affection and carrier mutation statuses of family members. Probands from each pedigree are indicated using red color.

When object inlcudes `carrp.geno` and/or `carrp.pheno` generated by `carrierprob` function, the `plot` function displays the carrier probabilities for those with missing carrier status.

plot.simfam_tvc *Plot method for* simfam_tvc *or Plot pedigrees*

Description

Provides pedigree plots for specified families generated from simfam_tvc function with option to save plots into a pdf file.

Usage

```
## S3 method for class 'simfam_tvc'
plot(x, famid, pdf = FALSE, file = NULL, ...)
```

Arguments

x	An object of class 'simfam_tvc' created by simfam_tvc function or a data frame that has class attributes c("simfam_tvc", "data.frame").
famid	List of family IDs to plot. Default is the first family in given data set.
pdf	Logical; if TRUE, pedigree plots are saved in a pdf file. If FALSE, plot pedigrees on current plotting device. Default is FALSE.
file	File name to save the pedigree plots; Default file name is "pedigreeplot.pdf".
...	Additional arguments passed on to the plot function.

Details

Argument x can be a data frame that contains famID, indID, fatherID, motherID, gender (1 for male, 0 for female), status (1 for affected, 0 for non-affected), mgene (1 for mutation carrier, 0 for non-carrier, NA for missing), and proband (1 for proband, 0 for non-proband) and should have class attributes class(x) <- c("simfam", "data.frame").

Optionally, the data frame can contain a column named carrp.geno or carrp.pheno to replace missing values in mgene with their carrier probabilities.

Value

Returns pedigree plots for specified families created by simfam_tvc function or for the data frame provided along with the affection and carrier mutation statuses of family members. Probands from each pedigree are indicated using red color.

When object inlcudes carrp.geno and/or carrp.pheno generated by carrierprob function, the plot function displays the carrier probabilities for those with missing carrier status.

print.penmodel *Print method for* penmodel.

Description

Prints a summary of parameter estimates of a fitted penetrance model.

Usage

```
## S3 method for class 'penmodel'
print(x, digits = max(3, getOption("digits") - 3), ...)
```

Arguments

x	An object class of 'penmodel', a fitted model by penmodel or penmodelEM functions.
digits	Number of significant digits to use when printing.
...	Further arguments passed to or from other methods.

Value

Prints a short summary of the model and model fit.

Returns an object of class 'penmodel'.

print.penmodel_cmp *Print method for* penmodel_cmp.

Description

Prints a summary of parameter estimates of a fitted competing risk penetrance model.

Usage

```
## S3 method for class 'penmodel_cmp'
print(x, digits = max(3, getOption("digits") - 3), ...)
```

Arguments

x	An object class of 'penmodel_cmp', a fitted model by penmodel_cmp function.
digits	Number of significant digits to use when printing.
...	Further arguments passed to or from other methods.

Value

Prints a short summary of the model and model fit.

Returns an object of class 'penmodel_cmp'.

`print.summary.penmodel` *Print method for* `summary.penmodel` *of a fitted penetrance model.*

Description

Prints a short summary of parameter and penetrance estimates of a `'summary.penmodel'` object.

Usage

```
## S3 method for class 'summary.penmodel'
print(x, digits = max(3, getOption("digits") - 3),
  signif.stars=TRUE, ...)
```

Arguments

`x`	An object class of `'summary.penmodel'`, a result of a call to `summary.penmodel`.
`digits`	Number of significant digits to use when printing.
`signif.stars`	Logical; if `TRUE`, provides stars to hightlight significant p-values. Default is `TRUE`.
`...`	Further arguments passed to or from other methods.

Value

Prints a summary of parameter estimates, their standard errors, t-statistics and corresponding two-sided p-values and additionally indicates significance stars if `signif.stars` is `TRUE`.

Also prints penetrance estimates by age 70 specific to gender and mutation-status subgroups along with their standard errors and 95% confidence intervals.

Returns an object of class `'summary.penmodel'`.

print.summary.penmodel_cmp *Print method for* summary.penmodel_cmp *of a fitted competing risks penetrance model.*

Description

Prints a short summary of parameter and penetrance estimates of a 'summary.penmodel_cmp' object.

Usage

```
## S3 method for class 'summary.penmodel_cmp'
print(x, digits = max(3, getOption("digits") - 3),
  signif.stars=TRUE, ...)
```

Arguments

x	An object class of 'summary.penmodel_cmp', a result of a call to summary.penmodel_cmp.
digits	Number of significant digits to use when printing.
signif.stars	Logical; if TRUE, provides stars to hightlight significant p-values. Default is TRUE.
...	Further arguments passed to or from other methods.

Value

Prints a summary of parameter estimates, their standard errors, t-statistics and corresponding two-sided p-values and additionally indicates significance stars if signif.stars is TRUE.

Also prints penetrance estimates for each event by age 70 specific to gender and mutation-status subgroups along with their standard errors and 95% confidence intervals.

Returns an object of class 'summary.penmodel_cmp'.

simfam *Generate familial time-to-event data*

Description

Generates familial time-to-event data for specified study design, genetic model and source of residual familial correlation; the generated data frame also contains family structure (individual's id, father id, mother id, relationship to proband, generation), gender, current age, genotypes of major or second genes.

Usage

```
simfam(N.fam, design = "pop", variation = "none", interaction = FALSE,
       add.x = FALSE, x.dist = NULL, x.parms = NULL, depend = NULL,
       base.dist = "Weibull", frailty.dist = NULL, base.parms = c(0.016, 3),
       vbeta = c(1, 1),
       allelefreq = 0.02, dominant.m = TRUE, dominant.s = TRUE,
       mrate = 0, hr = 0, probandage = c(45, 2), agemin = 20, agemax = 100)
```

Arguments

N.fam	Number of families to generate.
design	Family based study design used in the simulations. Possible choices are: "pop", "pop+", "cli", "cli+", "twostage", or "noasc", where "pop" is for the population-based design that families are ascertained by affected probands, "pop+" is similar to "pop" but with mutation carrier probands, "cli" is for the clinic-based design that includes affected probands with at least one parent and one sib affected, "cli+" is similar to "cli" but with mutation carrier probands, "twostage" for two-stage design that randomly samples families from the population in the first stage and oversamples high risk families in the second stage that include at least two affected members in the family, and "noasc" for no ascertainment correction that families are from simple random sampling. Default is "pop".
variation	Source of residual familial correlation. Possible choices are: "frailty" for frailty shared within families, "secondgene" for second gene variation, "kinship" for correlated frailties within families with kinship matrix, or "none" for no residual familial correlation. Default is "none".
interaction	Logical; if TRUE, allows the interaction between gender and mutation status. Default is FALSE.
add.x	Logical; if TRUE, generates a covariate in addition to gender and majorgene. Default is FALSE.
x.dist	Distribution of the covairate. Possible choices to generate the covariate are: "normal" from normal distribution and "binomial" from binominal distribution. Default is NULL.

x.parms	Parameter values for the specified distribution of the covariate. x.parms = c(mean, sd) should be specified for x.dist = "normal" and x.parms = c(size, probs) should be specified for "binomial"; when size = 1, it generates binary covariate. Default is NULL.
depend	Inverse of variance of the frailty distribution. Dependence within families decreases with depend value. Default is NULL. Value should be specified as a positive real number when variation = "frailty" or variation = "kinship".
base.dist	Choice of baseline hazard distribution. Possible choices are: "Weibull", "loglogistic", "Gompertz", "lognormal" "gamma", "logBurr". Default is "Weibull".
frailty.dist	Choice of frailty distribution. Possible choices are: "gamma" or "lognormal" when variation="frailty". Default is NULL.
base.parms	Vector of parameter values for the specified baseline hazard function. base.parms = c(lambda, rho) should be specified for base.dist = "Weibull", "loglogistic", "Gompertz", "gamma", and "lognormal". For base.dist = "logBurr", three parameters should be specified base.parms = c(lambda, rho, eta). Default value is base.parms = c(0.016, 3) for base.dist = "Weibull".
vbeta	Vector of regression coefficients for gender, majorgene, interaction between gender and majorgene (if interaction = TRUE), secondgene (if variation = "secondgene"), and additional covariate (if add.x = TRUE).
allelefreq	Population allele frequencies of major disease gene. Value should be between 0 and 1. Vector of population allele frequencies of major and second disease genes should be provided when variation = "secondgene". Default value is allelefreq = 0.02.
dominant.m	Logical; if TRUE, the genetic model of major gene is dominant, otherwise recessive.
dominant.s	Logical; if TRUE, the genetic model of second gene is dominant, otherwise recessive.
mrate	Proportion of missing genotypes, value between 0 and 1. Default value is 0.
hr	Proportion of high risk families, which include at least two affected members, to be sampled from the two stage sampling. This value should be specified when design="twostage". Default value is 0. Value should lie between 0 and 1.
probandage	Vector of mean and standard deviation for the proband age. Default values are mean of 45 years and standard deviation of 2 years, probandage = c(45, 2).
agemin	Minimum age of disease onset or minimum age. Default is 20 years of age.
agemax	Maximum age of disease onset or maximum age. Default is 100 years of age.

Details

The design argument defines the type of family based design to be simulated. Two variants of the population-based and clinic-based design can be chosen: "pop" when proband is affected, "pop+" when proband is affected mutation carrier, "cli" when proband is affected and at least one parent and one sibling are affected, "cli+" when proband is affected mutation-carrier and at least one parent and one sibling are affected. The two-stage design, "twostage", is used to oversample high risk families, where the proportion of high risks families to include in the sample is specified by hr.

High risk families often include multiple (at least two) affected members in the family. `design = "noasc"` is to be used for no ascertainment correction.

The ages at onset are generated from the following penetrance models depending on the choice of `variation = "none", "frailty", "secondgene", "kinship".`. When `variation = "none"`, the ages at onset are independently generated from the proportional hazard model conditional on the gender and carrier status of major gene mutation, $X = (x_s, x_g)$. The ages at onset correlated within families are generated from the shared frailty model (`variation = "frailty"`) , the correlated shared frailty model with kinship matrix (`variation = "kinship"`), or the two-gene model (`variation = "secondene"`), where the residual familial correlation is induced by a frailty or a second gene, respectively, shared within the family.

The proportional hazard model

$$h(t|X) = h_0(t - t_0) \exp(\beta_s x_s + \beta_g x_g),$$

where $h_0(t)$ is the baseline hazard function, t_0 is a minimum age of disease onset, x_s and x_g indicate male (1) or female (0) and carrier (1) or non-carrier (0) of a main gene of interest, respectively.

The shared frailty model

$$h(t|X, Z) = h_0(t - t_0) Z \exp(\beta_s x_s + \beta_g x_g),$$

where $h_0(t)$ is the baseline hazard function, t_0 is a minimum age of disease onset, Z represents a frailty shared within families and follows either a gamma or log-normal distribution, x_s and x_g indicate male (1) or female (0) and carrier (1) or non-carrier (0) of a main gene of interest, respectively.

The correlated shared frailty model with kinship matrix

$$h(t|X, Z) = h_0(t - t_0) Z \exp(\beta_s x_s + \beta_g x_g),$$

where $h_0(t)$ is the baseline hazard function, t_0 is a minimum age of disease onset, Z represents a vector of frailties following a multivariate log-normal distribution with mean 0 and variance $2 * K/depend$, where K represents the kinship matrix, x_s and x_g indicate male (1) or female (0) and carrier (1) or non-carrier (0) of a main gene of interest, respectively.

The two-gene model

$$h(t|X, Z) = h_0(t - t_0) Z \exp(\beta_s x_s + \beta_1 x_1 + \beta_2 x_2),$$

where x_1, x_2 indicate carriers (1) and non-carriers (0) of a major gene and of second gene mutation, respectively.

The current ages for each generation are simulated assuming normal distributions. However, the probands' ages are generated using a left truncated normal distribution as their ages cannot be less than the minimum age of onset. The average age difference between each generation and their parents is specified as 20 years apart.

Note that simulating family data under the clinic-based designs (`"cli"` or `"cli+"`) or the two-stage design can be slower since the ascertainment criteria for the high risk families are difficult to meet in such settings. Especially, `"cli"` design could be slower than `"cli+"` design since the proband's mutation status is randomly selected from a disease population in `"cli"` design, so his/her family members are less likely to be mutation carriers and have less chance to be affected, whereas the

probands are all mutation carriers, their family members have higher chance to be carriers and affected by disease. Therefore, "cli" design requires more iterations to sample high risk families than "cli+" design.

Value

Returns an object of class 'simfam', a data frame which contains:

famID	Family identification (ID) numbers.
indID	Individual ID numbers.
gender	Gender indicators: 1 for males, 0 for females.
motherID	Mother ID numbers.
fatherID	Father ID numbers.
proband	Proband indicators: 1 if the individual is the proband, 0 otherwise.
generation	Individuals generation: 1=parents of probands,2=probands and siblings, 3=children of probands and siblings.
majorgene	Genotypes of major gene: 1=AA, 2=Aa, 3=aa where A is disease gene.
secondgene	Genotypes of second gene: 1=BB, 2=Bb, 3=bb where B is disease gene.
ageonset	Ages at disease onset in years.
currentage	Current ages in years.
time	Ages at disease onset for the affected or ages of last follow-up for the unaffected.
status	Disease statuses: 1 for affected, 0 for unaffected (censored).
mgene	Major gene mutation indicators: 1 for mutated gene carriers, 0 for mutated gene noncarriers, or NA if missing.
relation	Family members' relationship with the proband:

1	Proband (self)
2	Brother or sister
3	Son or daughter
4	Parent
5	Nephew or niece
6	Spouse
7	Brother or sister in law

fsize	Family size including parents, siblings and children of the proband and the siblings.
naff	Number of affected members in family.
weight	Sampling weights.

`simfam2` *Generate familial time-to-event data with Kinship or IBD matrices.*

Description

Generate familial time-to-event data from correlated fraily model with Kinship or/and IBD matrices given pedigree data.

Usage

```
simfam2(inputdata = NULL, IBD = NULL, design = "pop", variation = "none", depend = NULL,
base.dist = "Weibull", base.parms = c(0.016, 3), var_names = c("gender", "mgene"),
vbeta = c(1, 1), agemin = 20, hr = NULL)
```

Arguments

`inputdata`	Dataframe contains variables `famID`, `indID`, `gender`, `motherID`, `fatherID`, `proband`, `generation`, `currentage` and other variables to be used in generating time-to-event data.
`IBD`	IBD matrix
`design`	Family based study design used in the simulations. Possible choices are: `"pop"`, `"pop+"`, `"cli"`, `"cli+"`, `"twostage"`, or `"noasc"`, where `"pop"` is for the population-based design that families are ascertained by affected probands, `"pop+"` is similar to `"pop"` but with mutation carrier probands, `"cli"` is for the clinic-based design that includes affected probands with at least one parent and one sib affected, `"cli+"` is similar to `"cli"` but with mutation carrier probands, `"twostage"` for two-stage design that randomly samples families from the population in the first stage and oversamples high risk families in the second stage that include at least two affected members in the family, and `"noasc"` for no ascertainment correction that families are from simple random sampling. Default is `"pop"`.

variation	Source of residual familial correlation. Possible choices are: "kinship" for correlated frailties within families generated by kinship matrix, "IBD" for correlated frailties by IBD matrix, c("kinship", "IBD") by both kinship and IBD matrices, or "none" for no residual familial correlation. Default is "none".
depend	Inverse of variance for the frailty distribution. A single value should be specified when variation = "IBD" or variation = "kinship" or a vector of two values when variation = c("kinship", "IBD"), where the first element corresponds to kinship matrix and the second element corresponds to IBD matrix. Default is NULL.
base.dist	Choice of baseline hazard distribution. Possible choices are: "Weibull", "loglogistic", "Gompertz", "lognormal" "gamma", "logBurr". Default is "Weibull".
base.parms	Vector of parameter values for the specified baseline hazard function. base.parms = c(lambda, rho) should be specified for base.dist = "Weibull", "loglogistic", "Gompertz", "gamma", and "lognormal". For base.dist = "logBurr", three parameters should be specified base.parms = c(lambda, rho, eta). Default value is base.parms = c(0.016, 3) for base.dist = "Weibull".
var_names	Names of variables to be used in generating time-to-event data. Specified variables should be part of inputdata.
vbeta	Vector of regression coefficients for the variables specified by var_names.
hr	Proportion of high risk families, which include at least two affected members, to be sampled from the two stage sampling. This value should be specified when design="twostage". Default value is 0. Value should lie between 0 and 1.
agemin	Minimum age of disease onset or minimum age. Default is 20 years of age.

Details

The ages at onset are generated from the correlated frailties and covariates using the following model:

The correlated shared frailty model with kinship and/or IBD matrices

$$h(t|X, Z) = h_0(t - t_0)Z \exp(X\beta),$$

where $h_0(t)$ is the baseline hazard function, t_0 is a minimum age of disease onset, Z represents a vector of frailties following a multivariate log-normal distribution with mean 0 and variance $2 * K * sig1 + D * sig2$, where K represents the kinship matrix and D is IBD matrix, $sig1$ and $sig2$ are variance components related to each matrix and their values are specified by depend = c(1/sig1, 1/sig2), and X represents a vector of variables whose names are specified by var_names, and β is a vector of corresponding coefficients whose values are specified by vbeta.

The variance structure of the frailties shared within families is chosen by either variation = "kinship" or "IBD" matrix or both variation = c("kinship", "IBD").

When variation = "none", the ages at onset are independently generated from the proportional hazard model conditional on the covariates X.

The design argument defines the type of family based design to be simulated. Two variants of the population-based and clinic-based design can be chosen: "pop" when proband is affected, "pop+" when proband is affected mutation carrier, "cli" when proband is affected and at least one parent and one sibling are affected, "cli+" when proband is affected mutation-carrier and at least one

parent and one sibling are affected. The two-stage design, "twostage", is used to oversample high risk families, where the proportion of high risks families to include in the sample is specified by hr. High risk families often include multiple (at least two) affected members in the family. design = "noasc" is to be used for no ascertainment correction.

Value

Returns an object of class 'simfam', a data frame which contains inputdata and the following:

ageonset	Ages at disease onset in years.
time	Ages at disease onset for the affected or ages of last follow-up for the unaffected.
status	Disease statuses: 1 for affected, 0 for unaffected (censored).
fsize	Family size including parents, siblings and children of the proband and the siblings.
naff	Number of affected members in family.
weight	Sampling weights.

simfam_cmp *Generate familial competing risks data*

Description

Generates familial competing risks data for specified study design, genetic model and source of residual familial correlation; the generated data frame has the same family structure as that simfam function, including individual's id, father id, mother id, relationship to proband, generation, gender, current age, genotypes of major or second genes.

Usage

```
simfam_cmp(N.fam, design = "pop+", variation = "none", interaction = FALSE,
       depend = NULL, base.dist = c("Weibull", "Weibull"), frailty.dist = "none",
         base.parms = list(c(0.016, 3), c(0.016, 3)),
      vbeta = list(c(-1.13, 2.35), c(-1, 2)), allelefreq = 0.02, dominant.m = TRUE,
         dominant.s = TRUE, mrate = 0, hr = 0, probandage = c(45, 2),
         agemin = 20, agemax = 100)
```

Arguments

N.fam	Number of families to generate.
design	Family based study design used in the simulations. Possible choices are: "pop", "pop+", "cli", "cli+" or "twostage", where "pop" is for the population-based design that families are ascertained by affected probands, "pop+" is similar to "pop" but with mutation carrier probands, "cli" is for the clinic-based design that includes affected probands with at least one parent and one sib affected, "cli+" is similar to "cli" but with mutation carrier probands and "twostage" for two-stage design that randomly samples families from the population in the first stage and oversamples high risk families in the second stage that include at least two affected members in the family. Default is "pop+".
variation	Source of residual familial correlation. Possible choices are: "frailty" for frailty shared within families, "secondgene" for second gene variation, or "none" for no residual familial correlation. Default is "none".
interaction	Logical; if TRUE, allows the interaction between gender and mutation status. Two logical values should be specified for each competing event; if only one logical value is provided, the same logical value will be assumed for both events. Default is FALSE.

depend	Two values shoud be specified for each competing event when `frailty.dist = "gamma"` or `frailty.dist = "lognormal"`, three values should be specified with `frailty.dist = "cgamma"` or `frailty.dist = "clognormal"`. The first two values represent the inverse of the variance for each competing event and the third value represents the correlation between the two events.
base.dist	Choice of baseline hazard distribution. Possible choices are: `"Weibull"`, `"loglogistic"`, `"Gompertz"`, `"lognormal" "gamma"`, `"logBurr"`. Default is `"Weibull"`. Two distributions should be specified for each competing event. If only one distribution is specified, the same distribution will be assumed for both events.
frailty.dist	Choice of frailty distribution. Possible choices are `"gamma"` for independent gamma, `"lognormal"` for independent lognormal, `"cgamma"` for correlated gamma, or `"clognormal"` for correlated lognormal distribution. Default is `NULL`.
base.parms	The list of two vectors of baseline parameters for each event should be specified. For example, `base.parms=list(c(lambda1, rho1), c(lambda2, rho2))` should be specified for `base.dist=c("Weibull", "Weibull")`. Two parameters `base.parms=c(lambda, rho)` should be specified for `base.dist="Weibull"`, `"loglogistic"`, `"Gompertz"`, `"gamma"`, and `"lognormal"`, and three parameters should be specified `base.parms = c(lambda, rho, eta)` for `base.dist="logBurr"`.
vbeta	List of two vectors of regression coefficients for each event should be specified. Each vector contains regression coefficients for gender, majorgene, interaction between gender and majorgene (if `interaction = TRUE`), and secondgene (if `variation = "secondgene"`).
allelefreq	Population allele frequencies of major disease gene. Value should be between 0 and 1. Vector of population allele frequencies for major and second disease genes should be provided when `variation = "secondgene"`. Default value is `allelefreq = 0.02`.
dominant.m	Logical; if `TRUE`, the genetic model of major gene is dominant, otherwise recessive.
dominant.s	Logical; if `TRUE`, the genetic model of second gene is dominant, otherwise recessive.
mrate	Proportion of missing genotypes, value between 0 and 1. Default value is 0.
hr	Proportion of high risk families, which include at least two affected members, to be sampled from the two stage sampling. This value should be specified when `design="twostage"`. Default value is 0. Value should lie between 0 and 1.
probandage	Vector of mean and standard deviation for the proband age. Default values are mean of 45 years and standard deviation of 2 years, `probandage = c(45, 2)`.
agemin	Minimum age of disease onset or minimum age. Default is 20 years of age.
agemax	Maximum age of disease onset or maximum age. Default is 100 years of age.

Details

Competing risk model

Event 1:

$$h(t|X, Z_1) = h_{01}(t - t_0)Z \exp(\beta_{s1}x_s + \beta_{g1}x_g),$$

Event 2:

$$h(t|X, Z_1) = h_{02}(t - t_0)Z \exp(\beta_{s2}x_s + \beta_{g2}x_g),$$

where $h_{01}(t)$ and $h_{02}(t)$ are the baseline hazard functions for event 1 and event 2, respectively, t_0 is a minimum age of disease onset, Z_1 and Z_2 are frailties shared within families for each event and follow either a gamma, log-normal, correlateg gamma, or correlated log-normal distributions, x_s and x_g indicate male (1) or female (0) and carrier (1) or non-carrier (0) of a main gene of interest, respectively.

Choice of frailty distributions for competing risk models

`frailty.dist = "gamma"` shares the frailties within families generated from a gamma distribution independently for each competing event, where Z_j follows Gamma(k_j, $1/k_j$).

`frailty.dist = "lognormal"` shares the frailties within families generated from a log-normal distribution independently for each competing event, where Z_j follows log-normal distribution with mean 0 and variance $(1/k_j$.

`frailty.dist = "cgamma"` shares the frailties within families generated from a correlated gamma distribution to allow the frailties between two events to be correlated, where the correlated gamma frailties (Z_1, Z_2) are generated with three independent gamma frailties (Y_0, Y_1, Y_2) as follows:

$Z_1 = (k_0/(k_0 + k_1)Y_0 + Y_1$

$Z_2 = (k_0/(k_0 + k_2)Y_0 + Y_2$

where Y_0 from Gamma(k_0, $1/k_0$);

Y_1 from Gamma(k_1, $1/(k_0 + k_1)$);

Y_2 from Gamma(k_2, $1/(k_0 + k_2)$).

`frailty.dist = "clognormal"` shares the frailties within families generated from a correlated log-normal distribution where $log(Z_j)$ follows a normal distribution with mean 0, variance $1/k_j$ and correlation between two events k_0.

`depend` should specify the values of related frailty parameters: `c(k1, k2)` with `frailty.dist = "gamma"` or `frailty.dist = "lognormal"`; `c(k1, k2, k0)` for `frailty.dist = "cgamma"` or `frailty.dist = "clognormal"`.

The current ages for each generation are simulated assuming normal distributions. However, the probands' ages are generated using a left truncated normal distribution as their ages cannot be less than the minimum age of onset. The average age difference between each generation and their parents is specified as 20 years apart.

The `design` argument defines the type of family based design to be simulated. Two variants of the population-based and clinic-based design can be chosen: `"pop"` when proband is affected, `"pop+"` when proband is affected mutation carrier, `"cli"` when proband is affected and at least one parent and one sibling are affected, `"cli+"` when proband is affected mutation-carrier and at least one parent and one sibling are affected. The two-stage design, `"twostage"`, is used to oversample high risk families, where the proportion of high risks families to include in the sample is specified by `hr`. High risk families often include multiple (at least two) affected members in the family.

Note that simulating family data under the clinic-based designs (`"cli"` or `"cli+"`) or the two-stage design can be slower since the ascertainment criteria for the high risk families are difficult to meet in such settings. Especially, `"cli"` design could be slower than `"cli+"` design since the proband's mutation status is randomly selected from a disease population in `"cli"` design, so his/her family

members are less likely to be mutation carriers and have less chance to be affected, whereas the probands are all mutation carriers, their family members have higher chance to be carriers and affected by disease. Therefore, "cli" design requires more iterations to sample high risk families than "cli+" design.

Value

Returns an object of class 'simfam', a data frame which contains:

famID	Family identification (ID) numbers.
indID	Individual ID numbers.
gender	Gender indicators: 1 for males, 0 for females.
motherID	Mother ID numbers.
fatherID	Father ID numbers.
proband	Proband indicators: 1 if the individual is the proband, 0 otherwise.
generation	Individuals generation: 1=parents of probands,2=probands and siblings, 3=children of probands and siblings.
majorgene	Genotypes of major gene: 1=AA, 2=Aa, 3=aa where A is disease gene.
secondgene	Genotypes of second gene: 1=BB, 2=Bb, 3=bb where B is disease gene.
ageonset	Ages at disease onset in years.
currentage	Current ages in years.
time	Ages at disease onset for the affected or ages of last follow-up for the unaffected.
status	Disease statuses: 1 for affected by event 1, 2 for affected by event 2, 0 for unaffected (censored).
mgene	Major gene mutation indicators: 1 for mutated gene carriers, 0 for mutated gene noncarriers, or NA if missing.
relation	Family members' relationship with the proband:

1 Proband (self)
2 Brother or sister
3 Son or daughter
4 Parent
5 Nephew or niece
6 Spouse
7 Brother or sister in law

fsize	Family size including parents, siblings and children of the proband and the siblings.
naff	Number of affected members by either event 1 or 2 within family.
df1	Number of affected members by event 1 within family.
df2	Number of affected members by event 2 within family.
weight	Sampling weights.

simfam_tvc *Generate familial time-to-event data with a time-varying covariate*

Description

Generates familial time-to-event data with a time-varying covariate for specified study design, genetic model and source of residual familial correlation; the generated data frame also contains family structure (individual's id, father id, mother id, relationship to proband, generation), gender, current age, genotypes of major or second genes.

Usage

```
simfam_tvc(N.fam, design = "pop", variation = "none", interaction = FALSE,
       add.x = FALSE, x.dist = NULL, x.parms = NULL, depend = NULL,
       add.tvc = FALSE, tvc.type = "PE", tvc.range = NULL, tvc.parms = 1,
       base.dist = "Weibull", frailty.dist = NULL, base.parms = c(0.016, 3),
       vbeta = c(1, 1),
       allelefreq = 0.02, dominant.m = TRUE, dominant.s = TRUE,
       mrate = 0, hr = 0, probandage = c(45, 2), agemin = 20, agemax = 100)
```

Arguments

N.fam	Number of families to generate.
design	Family based study design used in the simulations. Possible choices are: "pop", "pop+", "cli", "cli+", "twostage", or "noasc", where "pop" is for the population-based design that families are ascertained by affected probands, "pop+" is similar to "pop" but with mutation carrier probands, "cli" is for the clinic-based design that includes affected probands with at least one parent and one sib affected, "cli+" is similar to "cli" but with mutation carrier probands, "twostage" for two-stage design that randomly samples families from the population in the first stage and oversamples high risk families in the second stage that include at least two affected members in the family, and "noasc" for no ascertainment correction that families are from simple random sampling. Default is "pop".
variation	Source of residual familial correlation. Possible choices are: "frailty" for frailty shared within families, "secondgene" for second gene variation, "kinship" for correlated frailties within families with kinship matrix, or "none" for no residual familial correlation. Default is "none".

interaction	Logical; if TRUE, allows the interaction between gender and mutation status. Default is FALSE.
add.x	Logical; if TRUE, generates a covariate in addition to gender and majorgene. Default is FALSE.
x.dist	Distribution of the covairate. Possible choices to generate the covariate are: "normal" from normal distribution and "binomial" from binominal distribution. Default is NULL.
x.parms	Parameter values for the specified distribution of the covariate. x.parms = c(mean, sd) should be specified for x.dist = "normal" and x.parms = c(size, probs) should be specified for "binomial"; when size = 1, it generates binary covariate. Default is NULL.
depend	Inverse of variance of the frailty distribution. Dependence within families decreases with depend value. Default is NULL. Value should be specified as a positive real number when variation = "frailty" or variation = "kinship".
add.tvc	Logical; if TRUE, generates a time varying covariate. Default is FALSE.
tvc.type	Choice of time-varying covariate model. Possible choices are: "PE" and "CO". Default is "PE".
tvc.range	Range of ages at which the time-varying covariate occurs. Default is NULL.
tvc.parms	Vector of parameter values used for the time-varying covariate model. Default value is 1.
base.dist	Choice of baseline hazard distribution. Possible choices are: "Weibull", "loglogistic", "Gompertz", "lognormal" "gamma", "logBurr". Default is "Weibull".
frailty.dist	Choice of frailty distribution. Possible choices are: "gamma" or "lognormal" when variation="frailty". Default is NULL.
base.parms	Vector of parameter values for the specified baseline hazard function. base.parms = c(lambda, rho) should be specified for base.dist = "Weibull", "loglogistic", "Gompertz", "gamma", and "lognormal". For base.dist = "logBurr", three parameters should be specified base.parms = c(lambda, rho, eta). Default value is base.parms = c(0.016, 3) for base.dist = "Weibull".
vbeta	Vector of regression coefficients for gender, majorgene, interaction between gender and majorgene (if interaction = TRUE), secondgene (if variation = "secondgene"), and additional covariate (if add.x = TRUE).
allelefreq	Population allele frequencies of major disease gene. Value should be between 0 and 1. Vector of population allele frequencies of major and second disease genes should be provided when variation = "secondgene". Default value is allelefreq = 0.02.
dominant.m	Logical; if TRUE, the genetic model of major gene is dominant, otherwise recessive.
dominant.s	Logical; if TRUE, the genetic model of second gene is dominant, otherwise recessive.
mrate	Proportion of missing genotypes, value between 0 and 1. Default value is 0.
hr	Proportion of high risk families, which include at least two affected members, to be sampled from the two stage sampling. This value should be specified when design="twostage". Default value is 0. Value should lie between 0 and 1.

probandage	Vector of mean and standard deviation for the proband age. Default values are mean of 45 years and standard deviation of 2 years, probandage = c(45, 2).
agemin	Minimum age of disease onset or minimum age. Default is 20 years of age.
agemax	Maximum age of disease onset or maximum age. Default is 100 years of age.

Details

Time-varying covariate

When add.tvc = TRUE, the time at which the time-varying covariate (TVC) occurs, tvc.age, is generated from a uniform distribution with the range specified by tvc.range. A vector of minimum and maximum ages for the TVC should be specified in tve.range. When tvc.range = NULL, agemin and agemax are used as the range. In addition, tvc.type should be either "PE" or "CO" and the parameter values for the specified TVC type should be provided in tvc.parms.

tvc.type = "PE" represents a permanent exposure model for TVC which assumes that the effect of the TVC stays constant after tvc.age. The tvc.parms for the PE model should be specified as a single value, which represents log hazard ratio.

tvc.type = "CO" represents the Cox and Oaks model for TVC which assumes that the effect of the TVC decays exponentially over time in the form $\beta \exp(-(t - t^*)\eta) + \eta_0$, where t^* is the time at which the TVC occurs. The tvc.parms for the CO model should be specified by a vector of three parameters consisting of c(beta, eta, eta0).

Family-based study design

The design argument defines the type of family based design to be simulated. Two variants of the population-based and clinic-based design can be chosen: "pop" when proband is affected, "pop+" when proband is affected mutation carrier, "cli" when proband is affected and at least one parent and one sibling are affected, "cli+" when proband is affected mutation-carrier and at least one parent and one sibling are affected. The two-stage design, "twostage", is used to oversample high risk families, where the proportion of high risks families to include in the sample is specified by hr. High risk families often include multiple (at least two) affected members in the family. design = "noasc" is to be used for no ascertainment correction.

Penetrance model

The ages at onset are generated from the following penetrance models depending on the choice of variation = "none", "frailty", "secondgene", "kinship".. When variation = "none", the ages at onset are independently generated from the proportional hazard model conditional on the gender and carrier status of major gene mutation, $X = (x_s, x_g)$.

The ages at onset correlated within families are generated from the shared frailty model (variation = "frailty") , the correlated shared frailty model with kinship matrix (variation = "kinship"), or the two-gene model (variation = "secondene"), where the residual familial correlation is induced by a frailty or a second gene, respectively, shared within the family.

The proportional hazard model

$$h(t|X) = h_0(t - t_0) \exp(\beta_s x_s + \beta_g x_g),$$

where $h_0(t)$ is the baseline hazard function, t_0 is a minimum age of disease onset, x_s and x_g indicate male (1) or female (0) and carrier (1) or non-carrier (0) of a main gene of interest, respectively.

The shared frailty model

$$h(t|X,Z) = h_0(t-t_0)Z\exp(\beta_s x_s + \beta_g x_g),$$

where $h_0(t)$ is the baseline hazard function, t_0 is a minimum age of disease onset, Z represents a frailty shared within families and follows either a gamma or log-normal distribution, x_s and x_g indicate male (1) or female (0) and carrier (1) or non-carrier (0) of a main gene of interest, respectively.

The correlated shared frailty model with kinship matrix

$$h(t|X,Z) = h_0(t-t_0)Z\exp(\beta_s x_s + \beta_g x_g),$$

where $h_0(t)$ is the baseline hazard function, t_0 is a minimum age of disease onset, Z represents a vector of frailties following a multivariate log-normal distribution with mean 0 and variance $2 * K * depend$, where K represents the kinship matrix, x_s and x_g indicate male (1) or female (0) and carrier (1) or non-carrier (0) of a main gene of interest, respectively.

The two-gene model

$$h(t|X,Z) = h_0(t-t_0)Z\exp(\beta_s x_s + \beta_1 x_1 + \beta_2 x_2),$$

where x_1, x_2 indicate carriers (1) and non-carriers (0) of a major gene and of second gene mutation, respectively.

The current ages for each generation are simulated assuming normal distributions. However, the probands' ages are generated using a left truncated normal distribution as their ages cannot be less than the minimum age of onset. The average age difference between each generation and their parents is specified as 20 years apart.

Value

Returns an object of class `'simfam'`, a data frame which contains:

`famID`	Family identification (ID) numbers.
`indID`	Individual ID numbers.
`gender`	Gender indicators: 1 for males, 0 for females.
`motherID`	Mother ID numbers.
`fatherID`	Father ID numbers.
`proband`	Proband indicators: 1 if the individual is the proband, 0 otherwise.
`generation`	Individuals generation: 1=parents of probands,2=probands and siblings, 3=children of probands and siblings.
`majorgene`	Genotypes of major gene: 1=AA, 2=Aa, 3=aa where A is disease gene.
`secondgene`	Genotypes of second gene: 1=BB, 2=Bb, 3=bb where B is disease gene.
`ageonset`	Ages at disease onset in years.
`currentage`	Current ages in years.
`time`	Ages at disease onset for the affected or ages of last follow-up for the unaffected.
`status`	Disease statuses: 1 for affected, 0 for unaffected (censored).

mgene	Major gene mutation indicators: 1 for mutated gene carriers, 0 for mutated gene noncarriers, or NA if missing.
newx	Additional covariate when add.x = TRUE.
tvc.age	Age at which the time-varying covariate occurs when add.tvc = TRUE.
tvc.status	TVC status: 1 if tvc.age < time, 0 otherwise.
relation	Family members' relationship with the proband:

1 Proband (self)
2 Brother or sister
3 Son or daughter
4 Parent
5 Nephew or niece
6 Spouse
7 Brother or sister in law

fsize	Family size including parents, siblings and children of the proband and the siblings.
naff	Number of affected members in family.
weight	Sampling weights.

summary.penmodel *Summary method for class* penmodel

Description

Provides a summary of a fitted penetrance model.

Usage

```
## S3 method for class 'penmodel'
summary(object, correlation=FALSE, ...)
```

Arguments

object	An object class of 'penmodel', a fitted model by penmodel or penmodelEM functions.
correlation	Logical; if TRUE, returns the correlation matrix of the estimated parameters. Default is FALSE.
...	Further arguments passed to or from other methods.

Value

Returns the object of class 'summary.penmodel', including the following summary values:

estimates	List of parameter estimates of transformed baseline parameters and regression coefficients, their standard errors, their robust standard errors if robust=TRUE was selected when fitting the penetrance model, t-statistics and corresponding two-sided p-values.
varcov	Variance-covariance matrix of the parameter estimates.
varcov.robust	Robust variance-covariance matrix of the parameter estimates if robust = TRUE was selected when fitting the penetrance model.
correlation	Correlation matrix obtained from the variance-covariance matrix.
correlation.robust	Correlation matrix obtained from the robust variance-covariance matrix if robust = TRUE was selected when fitting the penetrance model.

summary.penmodel_cmp *Summary method for class* penmodel_cmp

Description

Provides a summary of a fitted competing risks penetrance model.

Usage

```
## S3 method for class 'penmodel_cmp'
summary(object, correlation=FALSE, ...)
```

Arguments

object	An object class of 'penmodel_cmp', a fitted model by penmodel_cmp function.
correlation	Logical; if TRUE, returns the correlation matrix of the estimated parameters. Default is FALSE.
...	Further arguments passed to or from other methods.

Value

Returns the object of class 'summary.penmodel_cmp', including the following summary values:

estimates	List of parameter estimates of transformed baseline parameters and regression coefficients, their standard errors, their robust standard errors if robust=TRUE was selected when fitting the penetrance model, t-statistics and corresponding two-sided p-values.
varcov	Variance-covariance matrix of the parameter estimates.
varcov.robust	Robust variance-covariance matrix of the parameter estimates if robust = TRUE was selected when fitting the penetrance model.
correlation	Correlation matrix obtained from the variance-covariance matrix.
correlation.robust	Correlation matrix obtained from the robust variance-covariance matrix if robust = TRUE was selected when fitting the penetrance model.

summary.simfam *Summary method for* simfam

Description

Provides a summary of simulated data.

Usage

```
## S3 method for class 'simfam'
summary(object, digits = max(3, getOption("digits") - 3), ...)
```

Arguments

object	An object class of 'simfam' generated from simfam function
digits	Number of significant digits to use when printing.
...	Further arguments passed to or from other methods.

Value

Displays a summary of simulated data and returns the following values:

num.fam	Number of families simulated.
avg.num.affected	Average number of affected individuals per family.
avg.num.carriers	Average number of mutation carriers per family.
avg.family.size	Average family size.
ave.ageonset	Average age of onset for affected individuals.
