Title Linear Predictive Models Based on the LIBLINEAR C/C++ Library

Version 2.10-24

Date 2024-09-13

Description A wrapper around the LIBLINEAR C/C++ library for machine learning (available at <https://www.csie.ntu.edu.tw/~cjlin/liblinear/>). LIBLINEAR is a simple library for solving large-scale regularized linear classification and regression. It currently supports L2-regularized classification (such as logistic regression, L2-loss linear SVM and L1-loss linear SVM) as well as L1-regularized classification (such as L2-loss linear SVM and logistic regression) and L2-regularized support vector regression (with L1- or L2-loss). The main features of LiblineaR include multi-class classification (one-vs-the rest, and Crammer & Singer method), cross validation for model selection, probability estimates (logistic regression only) or weights for unbalanced data. The estimation of the models is particularly fast as compared to other libraries.

heuristicC	<i>Fast Heuristics For The Estimation Of the C Constant Of A Support Vector Machine.</i>
------------	--

Description

heuristicC implements a heuristics proposed by Thorsten Joachims in order to make fast estimates of a convenient value for the C constant used by support vector machines. This implementation only works for linear support vector machines.

Usage

```
heuristicC(data)
```

Arguments

data a nxp data matrix. Each row stands for an example (sample, point) and each column stands for a dimension (feature, variable)

Value

A value for the C constant is returned, computed as follows:
 $\frac{1}{\frac{1}{n} \sum_{i=1}^n \sqrt{G[z,i]}}$ where $G = \text{data} \% * \%t(\text{data})$

Note

Classification models usually perform better if each dimension of the data is first centered and scaled. If data are scaled, it is better to compute the heuristics on the scaled data as well.

LiblineaR*Linear predictive models estimation based on the LIBLINEAR C/C++ Library.*

Description

LiblineaR allows the estimation of predictive linear models for classification and regression, such as L1- or L2-regularized logistic regression, L1- or L2-regularized L2-loss support vector classification, L2-regularized L1-loss support vector classification and multi-class support vector classification. It also supports L2-regularized support vector regression (with L1- or L2-loss). The estimation of the models is particularly fast as compared to other libraries. The implementation is based on the LIBLINEAR C/C++ library for machine learning.

Usage

```
LiblineaR(
  data,
  target,
  type = 0,
  cost = 1,
  epsilon = 0.01,
  svr_eps = NULL,
  bias = 1,
  wi = NULL,
  cross = 0,
```

```

    verbose = FALSE,
    findC = FALSE,
    useInitC = TRUE,
    ...
)

```

Arguments

data	a nxp data matrix. Each row stands for an example (sample, point) and each column stands for a dimension (feature, variable). Sparse matrices of class matrix.csr, matrix.csc and matrix.coo from package SparseM are accepted. Sparse matrices of class dgCMatix, dgRMatrix or dgTMatrix from package Matrix are also accepted. Note that C code at the core of LiblineaR package corresponds to a row-based sparse format. Hence, dgCMatix, dgTMatrix, matrix.csc and matrix.csr inputs are first transformed into matrix.csr or dgRMatrix formats, which requires small extra computation time.
target	a response vector for prediction tasks with one value for each of the n rows of data. For classification, the values correspond to class labels and can be a 1xn matrix, a simple vector or a factor. For regression, the values correspond to the values to predict, and can be a 1xn matrix or a simple vector.
type	LiblineaR can produce 10 types of (generalized) linear models, by combining several types of loss functions and regularization schemes. The regularization can be L1 or L2, and the losses can be the regular L2-loss for SVM (hinge loss), L1-loss for SVM, or the logistic loss for logistic regression. The default value for type is 0. See details below. Valid options are: for multi-class classification • 0 – L2-regularized logistic regression (primal) • 1 – L2-regularized L2-loss support vector classification (dual) • 2 – L2-regularized L2-loss support vector classification (primal) • 3 – L2-regularized L1-loss support vector classification (dual) • 4 – support vector classification by Crammer and Singer • 5 – L1-regularized L2-loss support vector classification • 6 – L1-regularized logistic regression • 7 – L2-regularized logistic regression (dual) for regression • 11 – L2-regularized L2-loss support vector regression (primal) • 12 – L2-regularized L2-loss support vector regression (dual) • 13 – L2-regularized L1-loss support vector regression (dual)
cost	cost of constraints violation (default: 1). Rules the trade-off between regularization and correct classification on data. It can be seen as the inverse of a regularization constant. See information on the 'C' constant in details below. A usually good baseline heuristics to tune this constant is provided by the heuristicC function of this package.
epsilon	set tolerance of termination criterion for optimization. If NULL, the LIBLINEAR defaults are used, which are: if type is 0, 2, 5 or 6 epsilon=0.01

if type is 1, 3, 4, 7, 12 or 13 $\epsilon = 0.1$

The meaning of ϵ is as follows:

if type is 0 or 2: $|f'(w)|_2 \leq \epsilon \times \min(pos, neg)/l \times |f'(w_0)|_2$, where f is the primal function and pos/neg are # of positive/negative data (default 0.01)

if type is 11: $|f'(w)|_2 \leq \epsilon \times |f'(w_0)|_2$, where f is the primal function (default 0.001)

if type is 1, 3, 4 or 7: Dual maximal violation $\leq \epsilon$ (default 0.1)

if type is 5 or 6: $|f'(w)|_\infty \leq \epsilon \times \min(pos, neg)/l \times |f'(w_0)|_\infty$, where f is the primal function (default 0.01)

if type is 12 or 13: $|f'(\alpha)|_1 \leq \epsilon \times |f'(\alpha_0)|_1$, where f is the dual function (default 0.1)

svr_eps	set tolerance margin (ϵ) in regression loss function of SVR. Not used for classification methods.
bias	if $bias > 0$, instance data becomes $[data; bias]$; if ≤ 0 , no bias term added (default 1).
wi	a named vector of weights for the different classes, used for asymmetric class sizes. Not all factor levels have to be supplied (default weight: 1). All components have to be named according to the corresponding class label. Not used in regression mode.
cross	if an integer value $k > 0$ is specified, a k -fold cross validation on data is performed to assess the quality of the model via a measure of the accuracy. Note that this metric might not be appropriate if classes are largely unbalanced. Default is 0.
verbose	if TRUE, information are printed. Default is FALSE.
findC	if <code>findC</code> is TRUE runs a cross-validation of cross folds to find the best cost (C) value (works only for type 0 and 2). Cross validation is conducted many times under parameters $C = start_C, 2*start_C, 4*start_C, 8*start_C, \dots$, and finds the best one with the highest cross validation accuracy. The procedure stops when the models of all folds become stable or C reaches the maximal value of 1024.
useInitC	if <code>useInitC</code> is TRUE (default) <code>cost</code> is used as the smallest <code>start_C</code> value of the search range (<code>findC</code> has to be TRUE). If <code>useInitC</code> is FALSE, then the procedure calculates a small enough <code>start_C</code> .
...	for backwards compatibility, parameter labels may be provided instead of target. A warning will then be issued, or an error if both are present. Other extra parameters are ignored.

Details

For details for the implementation of LIBLINEAR, see the README file of the original c/c++ LIBLINEAR library at <https://www.csie.ntu.edu.tw/~cjlin/liblinear/>.

Value

If `cross > 0`, the average accuracy (classification) or mean square error (regression) computed over cross runs of cross-validation is returned.

Otherwise, an object of class "LiblineaR" containing the fitted model is returned, including:

TypeDetail	A string describing the type of model fitted, as determined by type.
Type	An integer corresponding to type.
W	A matrix with the model weights. If bias > 0, W contains p+1 columns, the last being the bias term. The columns are named according to the names of data, if provided, or "Wx" where "x" ranges from 1 to the number of dimensions. The bias term is named "Bias". If the number of classes is 2, or if in regression mode rather than classification, the matrix only has one row. If the number of classes is k > 2 (classification), it has k rows. Each row i corresponds then to a linear model discriminating between class i and all the other classes. If there are more than 2 classes, rows are named according to the class i which is opposed to the other classes.
Bias	The value of bias
ClassNames	A vector containing the class names. This entry is not returned in case of regression models.

Note

Classification models usually perform better if each dimension of the data is first centered and scaled.

predict.LiblineaR	<i>Predictions with LiblineaR model</i>
-------------------	---

Description

The function applies a model (classification or regression) produced by the LiblineaR function to every row of a data matrix and returns the model predictions.

Usage

```

## S3 method for class 'LiblineaR'
predict(object, newx, proba = FALSE, decisionValues = FALSE, ...)

```

Arguments

object	Object of class "LiblineaR", created by LiblineaR.
newx	An n x p matrix containing the new input data. A vector will be transformed to a n x 1 matrix. Sparse matrices of class matrix.csr, matrix.csc and matrix.coo from package SparseM are accepted. Sparse matrices of class dgCMatrix, dgRMatrix or dgTMatrix from package Matrix are also accepted. Note that C code at the core of LiblineaR package corresponds to a row-based sparse format. Hence, dgCMatrix, dgTMatrix, matrix.csc and matrix.csr inputs are first transformed into matrix.csr or dgRMatrix formats, which requires small extra computation time.
proba	Logical indicating whether class probabilities should be computed and returned. Only possible if the model was fitted with type=0, type=6 or type=7, i.e. a Logistic Regression. Default is FALSE.

decisionValues Logical indicating whether model decision values should be computed and returned. Only possible for classification models (type<10). Default is FALSE.
 ... Currently not used

Value

By default, the returned value is a list with a single entry:

predictions A vector of predicted labels (or values for regression).

If proba is set to TRUE, and the model is a logistic regression, an additional entry is returned:

probabilities An n x k matrix (k number of classes) of the class probabilities. The columns of this matrix are named after class labels.

If decisionValues is set to TRUE, and the model is not a regression model, an additional entry is returned:

decisionValues An n x k matrix (k number of classes) of the model decision values. The columns of this matrix are named after class labels.

Note

If the data on which the model has been fitted have been centered and/or scaled, it is very important to apply the same process on the newx data as well, with the scale and center values of the training data.
