## Index

alpha2int

'Single Character' <-> Integer Conversion for Discrete Data

#### Description

Simple conversion functions for discrete data (e.g., time series), between 0:k integers and *single* letter characters.

## Usage

alpha2int(x, alpha)
int2alpha(i, alpha)

#### Arguments

Х	character vector of single letters.
alpha	the alphabet, as one character string
i	integer vector of numbers in 0:k.

#### Value

alpha2int(x,\*) returns an integer vector of the same length as x, consisting of values from 0:k where k + 1 is the length of the alphabet, nchar(alpha).

int2alpha(i,\*) returns a vector of *single letter* character of the same length as i.

## See Also

vlmc, and int2char() and its inverse, char2int(), both working with multi-character strings instead of vectors of single characters; further, alphabet.

```
alphabet <- "abcdefghijk"
(ch <- sample(letters[1:10], 30, replace = TRUE))
(ic <- alpha2int(ch, alphabet))
stopifnot(int2alpha(ic, alphabet) == ch)</pre>
```

alphabet

#### Description

Return the alphabet in use, as a vector of "characters".

#### Usage

```
alphabet(x, ...)
## S3 method for class 'vlmc'
alphabet(x, ...)
```

#### Arguments

х	any R object, currently only available for vlmc ones.
	potential further arguments passed to and from methods.

## Value

a character vector, say r, with length equal to the alphabet size. Currently, typically all r[i] are strings of just one character.

## See Also

alpha2int for conversion to and from integer codings.

## Examples

```
data(bnrf1)
vb <- vlmc(bnrf1EB, cutoff = 5)
alphabet(vb) # |--> "a" "c" "g" "t"
```

as.dendrogram.vlmc Dendrogram Construction from VLMCs

#### Description

This is a method for the as.dendrogram generic function

#### Usage

```
## S3 method for class 'vlmc'
as.dendrogram(object, ...)
```

#### Arguments

object	a vlmc object.
	further arguments passed to and from methods.

## Value

An object of class dendrogram, i.e. a nested list described on that page.

#### See Also

as.dendrogram, plot.dendrogram.

## Examples

```
data(presidents)
dpr <- factor(cut(presidents, c(0,45,70,100)), exclude=NULL)# NA = 4th level</pre>
(vlmc.pres <- vlmc(dpr))</pre>
draw(vlmc.pres)
(dv.dpr <- as.dendrogram(vlmc.pres))</pre>
str(dv.dpr)
str(unclass(dv.dpr))
plot(dv.dpr, type ="tr", nodePar = list(pch=c(1,16), cex = 1.5))
## Artificial example
f1 <- c(1,0,0,0); f2 <- rep(1:0, 2)
(dt1 <- c(f1, f1, f2, f1, f2, f2, f1))
(vlmc.dt1c01 <- vlmc(dts = dt1, cutoff.prune = 0.1))</pre>
(dvlmc <- as.dendrogram(vlmc.dt1c01))</pre>
str(dvlmc)
## not so useful:
plot(dvlmc, nodePar= list(pch=c(1,16)))
## complete disaster:
plot(dvlmc, type ="tr", nodePar= list(pch=c(1,16)))
## but this is not (yet) so much better (want the same angles to left
## and right!!
plot(dvlmc, type ="tr", nodePar = list(pch=c(1,16)), center=TRUE,
     main = format(vlmc.dt1c01$call))
mtext(paste("dt1 =", gsub(" ","",deparse(dt1,width=100))))
```

```
bnrf1
```

BNRF1 Gene DNA sequences: Epstein-Barr and Herpes

#### Description

Two gene DNA data "discrete time series",

bnrf1EB the BNRF1 gene from the Epstein-Barr virus,

bnrf1HV the BNRF1 gene from the herpes virus.

## deviance.vlmc

#### Usage

data(bnrf1)

## Format

The EB sequence is of length 3954, whereas the HV has 3741 nucleotides. Both are R factors with the four levels c("a", "c", "g", "t").

## Author(s)

Martin Maechler (original packaging for R).

## Source

See the references; data used to be at https://anson.ucdavis.edu/~shumway/tsa.html, and are now available in CRAN package **astsa**, e.g., bnrflebv.

#### References

Shumway, R. and Stoffer, D. (2000) *Time Series Analysis and its Applications*. Springer Texts in Statistics.

#### Examples

deviance.vlmc Compute the Deviance of a Fitted VLMC Object

## Description

Compute the Deviance, i.e., - 2 log[likelihood(\*)] of a fitted VLMC object. The log-likelihood is also known as "entropy".

#### Usage

```
## S3 method for class 'vlmc'
deviance(object, ...)
```

#### Arguments

object	typically the result of $vlmc()$ .
	possibly further arguments (none at the moment).

## Value

A number, the deviance, i.e., -2log.likelihood(\*). where the log.likelihood is really what we currently have as entropy().

#### Author(s)

Martin Maechler

## See Also

entropy, vlmc,residuals.vlmc

#### Examples

```
example(vlmc)
deviance(vlmc.pres)

devianceR <- function(object)
{
    dn <- dimnames(pr <- predict(object))
    -2 * sum(log(pr[cbind(2:nrow(pr), match(dn[[1]][-1], dn[[2]]))]))
}
all.equal(deviance(vlmc.pres), devianceR(vlmc.pres), tol = 1e-14)</pre>
```

draw.vlmc

Draw a "VLMC" Object (in ASCII) as Tree

#### Description

Draws a vlmc object, typically the result of vlmc(.), to the R console, using one line per node.

## Usage

6

#### draw.vlmc

#### Arguments

x	typically the result of vlmc().
kind	integer code for the "kind of drawing", in $\{0,1,2,3\}$ .
flag	logical;
show.hidden	integer code; if not 0, give some indications about hidden (final) nodes
cumulative	logical indicating if the cumulative counts should be shown for nonterminal nodes; the 'delta's can only be computed from the cumulative counts, i.e., cumulative = FALSE should be used only by the knowing one.
delta	logical indicating if delta, i.e. $\delta(n, p(n))$ should be computed and printed for each (non-root) node $n$ with parent $p(n)$ . Note that this does not really make sense when cumulative = FALSE.
debug	logical; if TRUE, some extraneous progress information is printed to the R con- sole.
	(potentially more arguments)

## Details

.....

.....

Note that the counts internally are stored "non-cumulatively", i.e., as *difference* counts which is useful for likelihood (ratio) computations. In the internal C code, the *difference* counts are originally computed by the comp\_difference() function after tree generation. draw(\*, cumulative = TRUE) internally calls the C function cumulate() for the cumulative sums.

#### Value

nothing is returned.

## Author(s)

Martin Maechler

#### See Also

vlmc.

```
example(vlmc)
draw(vlmc.dt1c01)
draw(vlmc.dt1c01, flag = FALSE)
draw(vlmc.dt1c01, kind = 1)
draw(vlmc.dt1)
draw(vlmc.dt1, show = 3)
draw(vlmc.dt1, cumulative = FALSE)
```

id2ctxt

## Description

Utility for converting a vlmc state ID to the corresponding context. Of rare interest to the average user.

## Usage

id2ctxt(id, m=nchar(alpha), alpha=NULL)

#### Arguments

id	integer, a context ID such as optionally returned by predict.vlmc.
m	integer, the alphabet length. Defaults to nchar(alpha), the alphabet size if that is given.
alpha	alphabet string

## Value

a list (if alpha is not specified) or character vector of the same length as id, giving the context (as integer vector or single string) of the corresponding id

## See Also

predict.vlmc(\*, type = "ID").

## Examples

```
id2ctxt(c(2,3,5,9), alpha = "Ab")
str(id2ctxt(c(2,3,5,9), 2))
```

int2char

Character - Integer Conversion

## Description

Simple conversion utilities for character to integer conversion and vice versa.

## Usage

int2char(i, alpha)
char2int(x, alpha)

## logLik

#### Arguments

i	integer vectors, typically in $0:m$ when alpha has $m+1$ letters.
alpha	character string with several letters, representing the alphabet.
х	character string, typically with letters from alpha.

## Value

int2char() gives a string (length 1 character) with as many characters as length(i), by 0-indexing into the alphabet alpha.

char2int() gives an integer vector of length nchar(x) of integer codes according to alpha (starting at 0 !).

#### See Also

int2alpha() (which is used by int2char) and its inverse, int2alpha(), both working with vectors of *single* characters instead of multi-character strings.

## Examples

```
char2int("vlmc", paste(letters, collapse=""))
int2char(c(0:3, 3:1), "abcd")
int2char(c(1:0,3,3), "abc") # to eat ;-)
```

logLik

Log Likelihood of and between VLMC objects

## Description

Compute the log-likelihood or "entropy" of a fitted vlmc object. This is a method for the generic logLik.

#### Usage

```
entropy(object)
## S3 method for class 'vlmc'
logLik(object, ...)
entropy2(ivlmc1, ivlmc2, alpha.len = ivlmc1[1])
```

## Arguments

object	typically the result of vlmc().
ivlmc1, ivlmc2	two vlmc (sub) trees, see vlmc.
alpha.len	positive integer specifying the alphabet length.
	(potentially more arguments; required by generic)

#### Details

The logLik.vlmc() method computes the log likelihood for a fitted vlmc object. entropy is an alias for logLik for reasons of back compatibility.

entropy2 is less clear ... ... [[[ FIXME ]]] ... ...

## Value

a negative number, in some contexts typically further divided by log(x\$alpha.len).

Note that the logLik method is used by the default method of the AIC generic function (from R version 1.4.x), and hence provides AIC(object) for vlmc objects. Also, since vlmc version 1.3-13, BIC() works as well.

## Author(s)

Martin Maechler

## See Also

deviance.vlmc, vlmc, draw.vlmc.

```
dd <- cumsum(rpois(999, 1.5)) %% 10
(vd <- vlmc(dd))
entropy(vd)# the bare number
logLik(vd)
logLik(vdL <- vlmc(dd, cutoff = 3))</pre>
entropy2(vd $vlmc.vec,
         vdL$vlmc.vec)
## AIC model selection:
f1 <- c(1,0,0,0) # as in example(vlmc)
f2 <- rep(1:0,2)
(dt1 <- c(f1,f1,f2,f1,f2,f2,f1))
AIC(print(vlmc(dt1)))
AIC(print(vlmc(dt1, cutoff = 2.6)))
AIC(print(vlmc(dt1, cutoff = 0.4)))# these two differ ``not really''
AIC(print(vlmc(dt1, cutoff = 0.1)))
## Show how to compute it from the fitted conditional probabilities :
logLikR <- function(x) {</pre>
    dn <- dimnames(pr <- predict(x))</pre>
    sum(log(pr[cbind(2:nrow(pr), match(dn[[1]][-1], dn[[2]]))]))
}
all.equal( logLikR(vd),
          c(logLik (vd)), tol=1e-10) # TRUE, they do the same
## Compare different ones: [cheap example]:
example(draw)
for(n in ls())
```

## OZrain

0Zrain

Daily Rainfall in Melbourne, Australia, 1981-1990

#### Description

Amount of daily rainfall in Melbourne, Australia, 1981-1990, measured in millimeters. The amounts are integers with many zeros and three days of more than 500mm rain.

#### Usage

data(OZrain)

#### Format

A time-series of length 3653 with the amount of daily rainfall in mm. Because of the two leap years 1984 and '88, we have constructed it with ts(\*, start=1981, frequency=365.25, end = 1981+(3653 - 1)/365.25).

## Note

There must be one extra observation since for the ten years with two leap years, there are only 3652 days. In 61 out of 100 days, there's no rain.

#### Source

'rainfall.dat' in Rob J. Hyndman's *Time Series Data Library*, currently available at https: //pkg.yangzhuoranyang.com/tsdl/

originally, Australian Bureau of Meteorology, https://www.abs.gov.au.

```
data(0Zrain)
(n <- length(0Zrain)) ## should be 1 more than
ISOdate(1990,12,31) - ISOdate(1981, 1,1)## but it's 2 ...</pre>
```

```
has.rain <- OZrain > 0
```

```
summary(0Zrain[has.rain])# Median = 18, Q3 = 50
table(rain01 <- as.integer(has.rain))
table(rain4c <- cut(0Zrain, c(-.1, 0.5, 18.5, 50.1, 1000)))</pre>
```

```
AIC(v1 <- vlmc(rain01))# cutoff = 1.92
AIC(v00 <- vlmc(rain01, cut = 1.4))
AIC(v0 <- vlmc(rain01, cut = 1.5))
hist(0Zrain)
hist(0Zrain, breaks = c(0,1,5,10,50,1000), xlim = c(0,100))
plot(0Zrain, main = "Rainfall 1981-1990 in Melbourne")
plot(0Zrain, log="y", main = "Non-0 Rainfall [LOG scale]")
l0Z <- lowess(log10(0Zrain[has.rain]), f= .05)
lines(time(0Zrain)[has.rain], 10^l0Z$y, col = 2, lwd = 2)
```

```
predict.vlmc
```

Prediction of VLMC for (new) Series

#### Description

Compute predictions on a fitted VLMC object for each (but the first) element of another discrete time series. Computes by default a matrix of prediction probabilities. The argument type allows other predictions such as the most probable "class" or "response", the context length (tree "depth"), or an "ID" of the corresponding context.

#### Usage

```
## S3 method for class 'vlmc'
predict(object, newdata,
        type = c("probs", "class","response", "id.node", "depth", "ALL"),
        se.fit = FALSE,
        allow.subset = TRUE, check.alphabet=TRUE,
        ...)
## S3 method for class 'vlmc'
fitted(object, ...)
```

#### Arguments

object	typically the result of vlmc().
newdata	a discrete "time series", a numeric, character or factor, as the dts argument of vlmc(.).
type	character indicating the type of prediction required, options given in the <i>Usage</i> section above, see also the <i>Value</i> section below. The default "probs" returns a matrix of prediction probabilities, whereas "class" or "response" give the corresponding most probable class. The value of this argument can be abbreviated.
se.fit	a switch indicating if standard errors are required. — NOT YET supported — .

. . .

#### Value

Depending on the type argument,

"probs"	an $n \times m$ matrix pm of (prediction) probabilities, i.e., all the rows of pm sum to 1.
	pm[i,k] is $\hat{P}[Y_i = k   Y_{i-1},]$ (and is therefore NA for i=1). The dimnames of pm are the values of newdata[] and the alphabet letters k.
"class", "respon	se"
	the corresponding most probable value of $Y[]$ ; as factor for "class" and as integer in $0:(m-1)$ for type = "response". If there is more than one most probable value, the first one is chosen.
"id.node"	an (integer) "ID" of the current context (= node of the tree represented VLMC).
"depth"	the context length, i.e., the depth of the Markov chain, at the current observation (of newdata).
"ALL"	an object of class "predict.vlmc", a list with the following components,
	<b>ID</b> integer vector as for type = "id.node",
	probs prediction probability matrix, as above,
	flags integer vector, non-zero for particular states only, rather for debugging.
	<b>ctxt</b> character, ctxt[i] a string giving the context (backwards) for newdata[i], using alphabet letters.
	<b>fitted</b> character with fitted values, i.e., the alphabet letter with the highest probability, using max.col where ties are broken at random.
	alpha, alpha.len the alphabet (single string) and its length.
	which has its own print method (print.predict.vlmc).

#### Note

The predict method and its possible arguments may still be developed, and we are considering to return the marginal probabilities instead of NA for the first value(s).

The print method print.predict.vlmc uses fractions from package MASS to display the probabilities Pr[X = j], for  $j \in \{0, 1, ...\}$ , as these are rational numbers, shown as fractions of integers.

## See Also

vlmc and residuals.vlmc. For simulation, simulate.vlmc.

#### Examples

```
f1 <- c(1,0,0,0)
f_2 <- rep(1:0,2)
(dt2 \le rep(c(f1, f1, f2, f1, f2, f2, f1), 2))
(vlmc.dt2c15 <- vlmc(dt2, cutoff = 1.5))</pre>
draw(vlmc.dt2c15)
## Fitted Values:
all.equal(predict(vlmc.dt2c15, dt2), predict(vlmc.dt2c15))
(pa2c15 <- predict(vlmc.dt2c15, type = "ALL"))</pre>
## Depth = context length ([1] : NA) :
stopifnot(nchar(pa2c15 $ ctxt)[-1] ==
          predict(vlmc.dt2c15, type = "depth")[-1])
same <- (ff1 <- pa2c15 $ fitted) ==</pre>
        (ff2 <- int2alpha(predict(vlmc.dt2c15, type ="response"), alpha="01"))</pre>
which(!same) #-> some are different, since max.col() breaks ties at random!
ndt2 <- c(rep(0,6),f1,f1,f2)
predict(vlmc.dt2c15, ndt2, "ALL")
(newdt2 <- sample(dt2, 17))</pre>
pm <- predict(vlmc.dt2c15, newdt2, allow.subset = TRUE)</pre>
summary(apply(pm, 1, sum))# all 1
predict(vlmc.dt2c15, newdt2, type = "ALL")
data(bnrf1)
(vbnrf <- vlmc(bnrf1EB))</pre>
(pA <- predict(vbnrf, bnrf1EB[1:24], type = "ALL"))</pre>
pc <- predict(vbnrf, bnrf1EB[1:24], type = "class")</pre>
pr <- predict(vbnrf, bnrf1EB[1:24], type = "resp")</pre>
stopifnot(as.integer (pc[-1]) == 1 + pr[-1],
          as.character(pc[-1]) == strsplit(vbnrf$alpha,NULL)[[1]][1 + pr[-1]])
##-- Example of a "perfect" fit -- just for illustration:
##
       the default, thresh = 2 doesn't fit perfectly(i=38)
(vlmc.dt2c0th1 <- vlmc(dt2, cutoff = 0, thresh = 1))</pre>
## "Fitted" = "Data" (but the first which can't be predicted):
stopifnot(dt2[-1] == predict(vlmc.dt2c0th1,type = "response")[-1])
```

prt.vvec

Recursively Print the VLMC Result Vector

#### Description

This is an auxiliary function which recursively displays (prints) the integer result vector of a vlmc fit.

14

## **RCplot**

## Usage

prt.vvec(v, nalph, pad=" ")

#### Arguments

v	<pre>typically x \$ vlmc.vec[ -1] where x is the result of vlmc(*).</pre>
nalph	alphabet size; typically x \$ vlmc.vec[1].
pad	character, to be used for padding paste(*, collapse=pad).

## See Also

summary.vlmc which uses prt.vvec.

## Examples

```
example(vlmc)
str(vv <- vlmc.dt1$vlmc)
prt.vvec(vv[-1], n = 2)
prt.vvec(vv[-1], n = 2, pad = " | ")</pre>
```

RCplot

Residuals vs Context plot

## Description

Plots the residuals of a fitted VLMC model against the contexts, i.e., produces a boxplot of residuals for all contexts used in the model fit.

This has proven to be useful function, and the many optional arguments allow quite a bit of customization. However, the current implementation is somewhat experimental and the defaults have been chosen from only a few examples.

#### Usage

## Arguments

х	an R object of class vlmc.
r2	numeric vector, by default of squared deviance residuals of x, but conceptually any (typically non-negative) vector of the appropriate length.
alphabet	the alphabet to use for labeling the contexts, via id2ctxt.
lab.horiz	logical indicating if the context labels should be written <b>horiz</b> ontally or vertically.
do.call	logical indicating if the vlmc call should be put as subtitle.
cex.axis	the character expansion for axis labeling, see also par. The default is only approximately good.
y.fact	numeric factor for expanding the space to use for the context labels (when lab.horiz is false).
col	color used for filling the boxes.
xlab	x axis label (with default).
main	main title to be used, NULL entailing a sensible default.
med.pars	graphical parameters to be used for coding of medians that are almost 0.
ylim	y range limits for plotting.
	further arguments to be passed to plot().

## Value

Invisibly, a list with components

k	the number of contexts (and hence box plots) used.
fID	a factor (as used in the interneal call to plot.factor).
rp	a list as resulting from the above call to $plot.factor()$ .

## References

Mächler M. and Bühlmann P. (2004) Variable Length Markov Chains: Methodology, Computing, and Software. J. Computational and Graphical Statistics 2, 435–455.

## See Also

summary.vlmc for other properties of a VLMC model.

## Examples

```
example(vlmc)
RCplot(vlmc.pres)
RCplot(vlmc.dt1c01)## << almost perfect fit (0 resid.)</pre>
```

16

residuals.vlmc

## Description

Compute residuals of a fitted vlmc object.

This is yet a matter of research and may change in the future.

#### Usage

```
## S3 method for class 'vlmc'
residuals(object,
        type = c("classwise",
                                "deviance", "pearson", "working", "response", "partial"),
        y = object$y, ...)
```

#### Arguments

object	typically the result of vlmc().
type	<ul> <li>The type of residuals to compute, defaults to "classwise" which returns an n × m matrix, see below. The other types only make sense when the discrete values of y are ordered which always includes the binary case (m = 2). The "deviance" residuals r are defined similarly as for logistic regression, see below.</li> <li>"pearson", "working" and "response" are currently identical and give the difference of the underlying integer code (of the discrete data). Note that "partial" residuals are not yet defined!</li> </ul>
v	discrete time series with respect to which the residuals are to be computed.
	possibly further arguments (none at the moment).

#### Value

If type = "classwise" (the default), a numeric matrix of dimension  $n \times m$  of values  $I_{i,j} - p_{i,j}$ where the indicator  $I_{i,j}$  is 1 iff y[i] == a[j] and a is the alphabet (or levels) of y, and  $p_{i,j}$  are the elements of the estimated (1-step ahead) predicted probabilities, p <- predict(object). Hence, for each *i*, the only positive residual stands for the observed class.

For all other types, the result is a numeric vector of the length of the original time-series (with first element NA).

For type = "deviance",  $r_i = \pm \sqrt{-2 \log(P_i)}$  where  $P_i$  is the predicted probability for the i-th observation which is the same as  $p_{i,y_i}$  above (now assuming  $y_i \in \{1, 2, ..., m\}$ ). The sum of the squared deviance residuals *is* the deviance of the fitted model.

#### Author(s)

Martin Maechler

## See Also

vlmc,deviance.vlmc, and RCplot for a novel residual plot.

#### Examples

simulate.vlmc Simulate a Discrete Time Series from fitted VLMC model

#### Description

Simulate from fitted VLMC model – basis of the VLMC bootstrap

#### Usage

#### Arguments

object	typically the result of vlmc().
nsim,n	non-negative integer, giving the length of the result. Note that n is deprecated and just there for back compatibility.
seed	random seed initializer; see simulate.
n.start	the number of initial values to be discarded (because of initial effects).
integer.return	logical; if TRUE, the result will be an integer vector with values in $0:(k-1)$ ; otherwise the resulting vector consists of letters from the alphabet x\$alpha.
keep.RSeed	logical indicating if the seed should be stored with the result (as 'required' by the generic simulate). Only set this FALSE with good reasons (back compatibility).
	(potentially further arguments for other simulate methods.

18

#### summary.vlmc

#### Details

The .Random.seed is used and updated as with other random number generation routines such as rbinom.

Note that if you want to simulate from a given start sequence x0, you'd use predict.vlmc(x, x0, type= "response") — actually not quite yet.

## Value

A "simulate.vlmc" object, basically a vector of length nsim. Either integer or character, depending on the integer.return argument, see above. Further, if keep.RSeed was true (as by default), a "seed" attribute with the random seed at the start of the simulation, for reproducibility.

#### Author(s)

Martin Maechler

## See Also

vlmc and predict.vlmc.

#### Examples

example(vlmc)

```
simulate(vlmc.dt1, 100)
simulate(vlmc.dt1c01, 100, int = TRUE)
# n.start = 0: 1st few observations will resemble the data
simulate(vlmc.dt1c01, 20, n.start=0, int = TRUE)
```

summary.vlmc Summary of Fitted Variable Length Markov Chain (VLMC)

## Description

Compute (and print) a summary of a vlmc object which is typically the result of vlmc(..).

#### Usage

vlmc

#### Arguments

object	an R object of class vlmc.
х	an R object of class summary.vlmc.
digits	integer giving the number of significant digits for printing numbers.
vvec.printing	logical indicating if the vvec component should be printed recursively via prt.vvec().
	potentially further arguments [Generic].

## Value

summary.vlmc() returns an object of class "summary.vlmc" for which there's a print method. It is basically a list containing all of object, plus additionally

confusion.table	
	the symmetric contingency table of data vs fitted.
depth.stats	<pre>statistics of Markov chain depth along the data; currently just summary(predict(object, type="depth")).</pre>
R2	the $R^2$ statistic, i.e. the percentage (in [0,1]) of correctly predicted data.

## See Also

vlmc, draw.vlmc.

## Examples

```
data(bnrf1)
vb <- vlmc(bnrf1EB)
svb <- summary(vb)
svb</pre>
```

vlmc

Fit a Variable Length Markov Chain (VLMC)

### Description

Fit a Variable Length Markov Chain (VLMC) to a discrete time series, in basically two steps: First a large Markov Chain is generated containing (all if threshold.gen = 1) the context states of the time series. In the second step, many states of the MC are collapsed by *pruning* the corresponding context tree.

Currently, the "alphabet" may contain can at most 26 different "character"s.

vlmc

## Usage

```
vlmc(dts,
    cutoff.prune = qchisq(alpha.c, df=max(.1,alpha.len-1),lower.tail=FALSE)/2,
    alpha.c = 0.05,
    threshold.gen = 2,
    code1char = TRUE, y = TRUE, debug = FALSE, quiet = FALSE,
    dump = 0, ctl.dump = c(width.ct = 1+log10(n), nmax.set = -1) )
is.vlmc(x)
## S3 method for class 'vlmc'
print(x, digits = max(3, getOption("digits") - 3), ...)
```

## Arguments

dts	a discrete "time series"; can be a numeric, character or factor.
cutoff.prune	non-negative number; the cutoff used for pruning; defaults to half the $\alpha$ -quantile of a chisq distribution, where $\alpha = alpha.c$ , the following argument:
alpha.c	number in (0,1) used to specify cutoff.prune in the more intuitive $\chi^2$ quantile scale; defaulting to 5%.
threshold.gen	integer >= 1 (usually left at 2). When <i>generating</i> the initial large tree, only generate nodes with count >= threshold.gen.
code1char	logical; if true (default), the data dts will beFIXME
у	logical; if true (default), the data dts will be returned. This allows to ensure that residuals (residuals.vlmc) and "k-step ahead" predictions can be computed from the result.
debug	logical; should debugging info be printed to stderr.
quiet	logical; if true, don't print some warnings.
dump	integer in 0:2. If positive, the pruned tree is dumped to stderr; if 2, the initial <b>un</b> pruned tree is dumped as well.
ctl.dump	integer of length 2, say ctl[1:2] controlling the above dump when dump > 0. ctl[1] is the width (number of characters) for the "counts", ctl[2] the max- imal number of set elements that are printed per node; when the latter is not positive (by default), currently $max(6, 15 - log10(n))$ is used.
x	a fitted "vlmc" object.
digits	integer giving the number of significant digits for printing numbers.
	potentially further arguments [Generic].

## Value

A "vlmc" object, basically a list with components

nobs	length of data series when fit. (was named "n" in earlier versions.)
threshold.gen,	cutoff.prune
	the arguments (or their defaults).
alpha.len	the alphabet size.

alpha	the alphabet used, as one string.
size	a named integer vector of length (>=) 4, giving characteristic sizes of the fitted VLMC. Its named components are
	"ord.MC" the (maximal) order of the Markov chain,
	"context" the "context tree size", i.e., the number of leaves plus number of "hidden nodes",
	"nr.leaves" is the number of leaves, and
	"total" the number of integers needed to encode the VLMC tree, i.e., length(vlmc.vec) (see below).
vlmc.vec	integer vector, containing (an encoding of) the fitted VLMC tree.
У	if y = TRUE, the data dts, as character, using the letters from alpha.
call	the call vlmc() used.

#### Note

Set cutoff = 0, thresh = 1 for getting a "perfect fit", i.e. a VLMC which perfectly re-predicts the data (apart from the first observation). Note that even with cutoff = 0 some pruning may happen, for all (terminal) nodes with  $\delta$ =0.

#### vlmc.version

```
table(dpres <- factor(dpres, exclude = NULL)) # NA as 4th level</pre>
levels(dpres)#-> make the alphabet -> warning
vlmc.pres <- vlmc(dpres, debug = TRUE)</pre>
vlmc.pres
## alphabet & and its length:
vlmc.pres$alpha
stopifnot(
 length(print(strsplit(vlmc.pres$alpha,NULL)[[1]])) == vlmc.pres$ alpha.len
)
## You now can use larger alphabets (up to 95) letters:
set.seed(7); it <- sample(40, 20000, replace=TRUE)</pre>
v40 <- vlmc(it)
v40
## even larger alphabets now give an error:
il <- sample(100, 10000, replace=TRUE)</pre>
ee <- tryCatch(vlmc(il), error= function(e)e)</pre>
stopifnot(is(ee, "error"))
```

vlmc.version Vers

## Version of VLMC Package

#### Description

Character string, giving the version number (and date) of the VLMC package.

#### Examples

```
vlmc.version
## Not run:
[1] "VLMC 1.3-14; after $Date: 2014/06/03 08:05:21 $ UTC"
## End(Not run)
```

vlmctree

Compute the tree structure of a "vlmc" object

## Description

Compute the tree representation of a "vlmc" object as R list.

#### Usage

```
vlmctree(x)
## S3 method for class 'vtree'
str(object, ...)
.vvec2tree(vv, k, chk.lev)
```

#### Arguments

x,object	typically the result of vlmc().
vv	integer vector encoding the fitted vlmc, typically x\$vlmc.vec[-1].
k	integer, the alphabet size.
chk.lev	integer internally used for consistency checking.
	further arguments passed to or from methods.

## Details

.vvec2tree is the internal (recursive) function building up the tree.

str.vtree is a method for the generic str function and typically for the output of vlmctree().
For each node, it gives the "parenting level" in braces and the counts.

## Value

A list of class "vtree" representing the tree structure recursively.

Each "node" of the tree is itself a list with components

level	length-2 integer giving the level in $\{0, 1,\}$ , counted from the root (which is $\emptyset$ ) and the parenting level, i.e the longest branch.
count	integer vector of length k where k is the number of "letters" in the alphabet.
total	equals to sum(* \$ count).
child	a list (of length k) of child nodes or NULL (i.e. not there).
