

Package ‘WRSS’

July 21, 2025

Type Package

Title Water Resources System Simulator

Depends R (>= 3.0.0), graphics, stats, Hmisc, nloptr

Version 3.1

Date 2022-05-17

Author Rezgar Arabzadeh; Parisa Aberi; Kaveh Panaghi; Shahab Araghinejad; Majid Montaseri

Maintainer Rezgar Arabzadeh <rezgararabzadeh@ut.ac.ir>

Description Water resources system simulator is a tool for simulation and analysis of large-scale water resources systems. 'WRSS' proposes functions and methods for construction, simulation and analysis of primary storage and hydropower water resources features (e.g. reservoirs, aquifers, and etc.) based on Standard Operating Policy (SOP).

WRSS-package

Water Resources System Simulator

Description

The WRSS is an object-oriented R package, which provides tools for simulation and analysis of large-scale supply and hydropower water resources systems. The package includes functions and methods for building, simulation, and visualization of water resources components.

Details

Package: WRSS
Type: Package
Version: 3.0
Date: 2022-05-17

License: GPL-3

the package includes three major types of functions as follows:

1- functions for construction and manipulation of water resources features:

- a) `createArea` constructor for basin/study area objects
- b) `createJunction` constructor for junction objects
- c) `createRiver` constructor for reach, river, and channel objects
- d) `createReservoir` constructor for reservoir objects
- e) `createDiversion` constructor for diversion objects
- f) `createAquifer` constructor for aquifer objects
- g) `createDemandSite` constructor for demand site objects
- h) `set.as` WRSS objects connector
- i) `addObjectToArea` adds objects form mentioned above constructors to a basin inherited from class of `createBasin`

2- functions for analysis and operation of water resources objects using Standard Operating Policy (SOP):

- a) `riverRouting` river operation using
- b) `reservoirRouting` reservoir operation
- c) `aquiferRouting` aquifer operation
- d) `diversionRouting` diversion operation
- e) `sim` simulates an objects inherited from class of `createArea`
- f) `rippl` computes no-failure storage volume using the sequent peak algorithm(SPA)
- g) `cap_design` computes RRV measures for a range of design parameters

3- functions for performance analysis and visualization.

- a) `plot.sim` plots the results of simulations for an object inherited from class of `sim`
- b) `plot.createArea` plots an object from class of `createArea`
- c) `risk` computes risk-based criateria for an object inherited from class of `sim`
- d) `GOF` Goodness of fit function

addObjectToArea	<i>Adds a feature to area</i>
-----------------	-------------------------------

Description

This function adds objects from the basin primary features to the object inherited from class of createArea.

Usage

```
addObjectToArea(area, object)
```

Arguments

area	An object inherited from createArea
------	---

object An objects inherited from any of the following constructors: [createAquifer](#), [createRiver](#), [createReservoir](#), [createJunction](#), [createDiversion](#), and [createDemandSite](#).

Details

The examples included in this documentation show construction and simulation of primary features of a water resources system using WRSS package. The Figure below presents schematic layouts attributed to the examples at the rest of the page:

Value

an object from class of createArea

aquiferRouting	<i>base function for aquifer simulation</i>
----------------	---

Description

Given a sort of demand(s), `aquiferRouting` function simulates a lumped and simple model of an unconfined aquifer under an optional given recharge time series, `rechargeTS`, and specific yield, `Sy`.

Usage

```

aquiferRouting(demand, priority = NA, area, volume,
               rechargeTS = NA, leakageFraction = NA,
               initialStorage = NA, Sy, simulation)

```

Arguments

<code>demand</code>	(optional) A matrix: is column-wise matrix of demands, at which the rows present demands for each monthly time step and columns are for different individual demand sites (MCM).
<code>priority</code>	(optional) A vector: is a vector of priorities associated to demand
<code>area</code>	The area of aquifer (Km ²)
<code>volume</code>	The aquifer volume (MCM)
<code>rechargeTS</code>	(optional) A vector : a vector of water flowing into the aquifer (MCM)
<code>leakageFraction</code>	(optional) The leakage coefficient of aquifer storage. The leakage is computed as the product of <code>leakageFraction</code> and aquifer storage. It is in $[0, 1]$ interval
<code>initialStorage</code>	(optional) The initial volume of aquifer at the first step of the simulation (MCM). If missing, the function iterates to carry over the aquifer

Sy	Specific yield (default: 0.1)
simulation	A list: simulation is a list of three vectors: start, end, and interval. the start and end components must be in 'YYYY-MM-DD' format. the interval component can takes either of 'day', 'week', or 'month'.

Value

the aquiferRouting function returns a list of objects as bellow:

- release: a matrix of release(s) equivalent to each demand (MCM)
- leakage: a vector of leakage time series (MCM)
- storage: a vector of storage time series (MCM)

```

`cap_design`*Constructor for class of cap_design*

Description

Calculates the RRV measures for multiple design candidates.

Usage

```
cap_design(area,params,w,plot)
```

Arguments

area	An object from class of 'createArea'
params	A list of list(s), which each sub-list can contains an object from either of classes 'createDemandSite' or 'createReservoir' and a vector of scale factors multiplied to the set design parameters. For reservoirs the scale factor will be multiplied to the capacity for the and for demand site, it will be multiplied to the demand time series
w	(optional) A vector of weights of sustainability indices summing 1 with length of equal with the number of demand site objects built-in 'params' argument or equal with number of demand sites supplied by the reservoirs built-in 'params'. If missing the weights will be assumed equal
plot	(optional) logical: plot the result or not. The default is TRUE

Value

A matrix of RRV and sustainability index proposed by Hashemitto et al. (1982) and Loucks (1997).

Author(s)

Rezgar Arabzadeh

createDemandSite	<i>Constructor for class of createDemandSite</i>
------------------	--

Description

this function constructs an object from class of createDemandSite, which represents a demand site such as domestic, agricultural, and etc, with a specified demand time series.

Usage

```
createDemandSite(name, demandTS, demandParams,
                 returnFlowFraction, suppliers,
                 downstream, priority)
```

Arguments

name	(optional) A string: the name of the demand site
demandTS	A vector: a vector of demand time series (MCM). If demandParams is null, providing the demandTS is compulsory.
demandParams	<p>A list: If demandTS is missing, the demandParams must be provided to establish demandTS. The demandParams includes three parts as follows:</p> <ul style="list-style-type: none"> • waterUseRate: The total water demand per hectare (MCM) per a given water cycle. • waterVariation: A vector of the percentages for water demand distribution within a water cycle (the percentages in each interval). For instance, if the cycle is annually and the interval is 'month'ly, the waterVariation could be a vector of length of 12, for which its indices signify the monthly portion of water demand, in percentage, by the total water demand required for the whole cycle. • cropArea: the area of cropping farms (in hectare).
returnFlowFraction	(optional) returnFlowFraction is fraction of total supplied water to the demand site. The return flow is computed as the product of returnFlowFraction and the amount of water the demand sites receives. returnFlowFraction must be in [0, 1] interval.
suppliers	(optional) A list of object(s) inherited from the following classes: createAquifer , createRiver , createReservoir , createDiversion .
downstream	(optional) An object from either of classes of createAquifer , createRiver , createReservoir , createJunction , createDiversion , or createDemandSite ; which return flow volume pours to it.
priority	(optional) An integer: the priority to be supplied. A value in [1, 99] interval.

createDemandSite.base *base function for class of createDemandSite*

Description

this function constructs an object from class of createDemandSite, which represents a demand site such as domestic, agricultural, and etc, with a specified demand time series.

Usage

```
## S3 method for class 'base'
createDemandSite(name, demandTS, demandParams,
                  returnFlowFraction, suppliers,
                  downstream, priority)
```

Arguments

name	(optional) A string: the name of the demand site
demandTS	A vector: a vector of demand time series (MCM). If demandParams is null, providing the demandTS is compulsory.
demandParams	A list: If demandTS is missing, the demandParams must be provided to establish demandTS. The demandParams includes three parts as follows: <ul style="list-style-type: none"> • waterUseRate: The total water demand per hectare (MCM) per a given water cycle • waterVariation: A vector of the percentages for water demand distribution within a water cycle (the percentages in each interval). For instance, if the cycle is annually and the interval is 'month'ly, the waterVariation could be a vector of length of 12, for which its indices signify the monthly portion of water demand, in percentage, by the total water demand required for the whole cycle • cropArea: the area of cropping farms (in hectare)
returnFlowFraction	(optional) returnFlowFraction is fraction of total supplied water to the demand site. The return flow is computed as the product of returnFlowFraction and the amount of water the demand sites receives. returnFlowFraction must be in [0, 1] interval.
suppliers	(optional) A list of object(s) inherited from the following classes: createAquifer , createRiver , createReservoir , createDiversion .

createDiversion	<i>Constructor for class of createDiversion</i>
-----------------	---

Description

this function constructs an object from class of createDiversion, acting as a diversion dam which is able to divert water up to a specified capacity.

Usage

```
createDiversion(name, capacity,
                divertObject, downstream, priority)
```

Arguments

name	(optional) A string: the name of the diversion
capacity	The maximum capacity of diversion dam (CMS).
divertObject	(optional) An object from either of classes of createAquifer , createRiver , createReservoir , createJunction , createDiversion , or createDemandSite ; which receives the diverted water volume.
downstream	(optional) An object from either of classes of createAquifer , createRiver , createReservoir , createJunction , createDiversion , or createDemandSite ; which overflow volume pours to it.
priority	(optional) An integer: the supplying priority. priority is a value in [1, 99] interval. If missing, the priority is set to Inf.

Value

An object from class of createDiversion

createDiversi.on.base *base function for class of createDiversi.on*

Description

this function constructs an object from class of createDiversi.on, acting as a diversion dam which is able to divert water up to a specified capacity.

Usage

```
## S3 method for class 'base'  
createDiversi.on(name, capacity,  
                 divertObject, downstream, priority)
```

Arguments

name	(optional) A string: the name of the diversion
capacity	The maximum capacity of diversion dam (CMS).
divertObject	(optional) An object from either of classes of createAquifer , createRiver , createReservoir , createJunction , createDiversi.on , or createDemandSite ; which receives the diverted water volume.
downstream	(optional) An object from either of classes of createAquifer , createRiver , createReservoir , createJunction , createDiversi.on , or createDemandSite ; which overflow volume pours to it.
priority	(optional) An integer: the supplying priority. priority is a value in [1, 99] interval. If missing, the priority is set to Inf.

Value

createReservoir	<i>Constructor for class of createReservoir</i>
-----------------	---

Description

this function constructs an object from class of createReservoir, which is able to simulate a storage reservoir under given a sort of demand(s).

Usage

```
createReservoir(type,
                name,
                priority,
                downstream,
                netEvaporation,
                seepageFraction,
                seepageObject,
                geometry,
                plant,
                penstock,
                initialStorage)
```

Arguments

type	A string: the type of the reservoir being instantiated: by default 'storage', however, it can be 'hydropower'
name	(optional) A string: the name of the reservoir.
priority	(optional) An integer: the supplying priority. priority is a value in [1, 99] interval. If missing, the priority is set to Inf.
downstream	(optional) An object; from either of classes of createAquifer , createRiver , createReservoir , createJunction , createDiversion , or createDemandSite ; which spillage volume pours to it.
netEvaporation	A vector: is a vector of net evaporation depth time series at the location of dam site (meter). If omitted, the evaporation is assumed to be zero.
seepageFraction	(optional) The seepage coefficient of reservoir storage. The seepage is computed as the product of seepageFraction and reservoir storage. It is in [0, 1] interval
seepageObject	(optional) An object; from either of classes of createAquifer , createRiver , createReservoir , createJunction , createDiversion , or createDemandSite ; which seepage volume pours to it.
geometry	A list of reservoir geometric specifications: <ul style="list-style-type: none"> • storageAreaTable: is a matrix whose first column includes reservoir volume (MCM) for different elevation levels and the second column contains reservoir area (in Km^2) corresponding to the first column

- storageElevationTable: is a matrix whose first column includes reservoir volume (MCM) for different elevation levels and the second column contains elevation (in meter) corresponding to the first column
 - dischargeElevationTable: is a matrix whose first column includes the capacity of reservoir tailwater discharge rate (in cms) for different elevation levels and the second column contains elevation levels corresponding to the first column, required if the type = 'hydropower' and the item submerged = TRUE
 - deadStorage: refers to water in a reservoir that cannot be drained by gravity through the dam outlet works (MCM)
 - capacity: The maximum capacity of the reservoir
- plant A list of power plant specifications. It is provided if type = 'hydropower':
- installedCapacity: the plant installed capacity (MW)
 - efficiency: is a matrix whose first column includes discharge rate (in cms) and the second column turbine efficiency, in [0 1] interval, corresponding to the first column
 - designHead: A vector of length of two, containing the minimum and maximum design water head (in meter) of the turbine respectively, that the it is in active state
 - designFlow: A vector of length of two, containing the minimum and maximum design flow rate (in cms) of the turbine respectively, that the it is in active state
 - turbineAxisElevation: The elevation of axis of the installed turbine (in meter)
 - submerged: logical: if the turbine is of type of submerged on, TRUE, otherwise, FALSE
 - loss: losses associated with the turbine (in meter)
- penstock (optional) A list of penstock specifications. It is provided if type = 'hydropower':
- diameter: The diameter of the penstock (in meter)
 - length: The length of the penstock (in meter)
 - roughness: pipe roughness coefficient used for Hazen-Williams formulation
- initialStorage (optional) The initial stored water at the reservoir in the first step of the simulation (MCM). If is missing the the function iterate to carry over the reservoir.

Value

An object from class of createReservoir

diversionRouting	<i>base function for diversion simulation</i>
------------------	---

Description

Given a sort of demand(s), diversionRouting function enable us to simulate the performance and effect of a diversion dam under a givn recharge time series, inflow, on the drainage network.

Usage

```
diversionRouting(demand=NA, priority = NA,  
                 capacity, inflow, simulation)
```

Arguments

demand	A matrix: is column-wise matrix of demands, at which the rows presents demands for each time step and columns are for different individual demand sites (MCM).
priority	A vector: is a vector of priorities associated to demand
capacity	The maximum capacity of diversion dam (CMS).
inflow	A vector : a vector of water flowing into the diversion (MCM)
simulation	A list: simulation is a list of three vectors: start, end, and interval. the start and end components must be in 'YYYY-MM-DD' format. the interval component can takes either of 'day', 'week', or 'month'.

Value

the diversionRouting function returns a list of features given as below:

- release : a matrix of release(s) equivalant to each demand (MCM)
- diverted: a vector of diverted volumes (MCM), release(s) are included
- overflow: a vector of overflow passing through the diversion (MCM)

GOF

*Goodness of fit***Description**

this function calculates the goodness of fit (gof) using chi-squared test.

Usage

```
GOF(basin,object,observed)
```

Arguments

basin	An object from class of sim.
object	An object from either of classes of createAquifer , createRiver , createReservoir , createJunction , createDiversion , or createDemandSite ; which is associated with observed time series and exists in the basin.
observed	A vector of observed time series.

Value

A list with class "htest".

reservoirRouting	<i>base function for reservoir simulation</i>
------------------	---

Description

Given a sort of demand(s), reservoirRouting function simulates the effect of a dam under given hydrometeorological time series, e.g. inflow and netEvaporation, on the drainage network.

Usage

```
reservoirRouting(type='storage',
                 inflow,
                 netEvaporation=NA,
                 demand=NA,
                 priority=NA,
                 seepageFraction=NA,
                 geometry=list(storageAreaTable=NULL,
                               storageElevationTable=NULL,
                               dischargeElevationTable=NULL,
                               deadStorage=0,
                               capacity=NULL),
                 plant=list(installedCapacity=NULL,
                             efficiency=NULL,
                             designHead=NULL,
                             designFlow=NULL,
                             turbineAxisElevation=NULL,
                             submerged=FALSE,
                             loss=0),
                 penstock=list(diameter=NULL,
                               length=0,
                               roughness=110),
                 initialStorage=NA,
                 simulation)
```

Arguments

type	A string: the type of the reservoir being instantiated: by default 'storage', however, it can be 'hydropower'
inflow	A vector : a vector of water flowing into the diversion (MCM)
netEvaporation	A vector: is a vector of net evaporation depth time series at the location of dam site (meter). If omitted, the evaporation is assumed to be zero.
demand	A matrix: is column-wise matrix of demands, at which the rows presents demands for each monthly time steps and columns are for different individual demand sites (MCM).
priority	(optional) A vector: is a vector of priorities associated to demand

seepageFraction	(optional) The seepage coefficient of reservoir storage. The seepage is computed as the product of seepageFraction and reservoir storage.
geometry	<p>A list of reservoir geometric specifications:</p> <ul style="list-style-type: none"> • storageAreaTable: is a matrix whose first column includes reservoir volume (MCM) for different elevation levels and the second column contains reservoir area (in Km²) corresponding to the first column • storageElevationTable: is a matrix whose first column includes reservoir volume (MCM) for different elevation levels and the second column contains elevation (in meter) corresponding to the first column • dischargeElevationTable: is a matrix whose first column includes the capacity of reservoir tailwater discharge rate (in cms) for different elevation levels and the second column contains elevation levels corresponding to the first column, required if the type = 'hydropower' and the item submerged = TRUE • deadStorage: refers to water in a reservoir that cannot be drained by gravity through the dam outlet works (MCM) • capacity: The maximum capacity of the reservoir
plant	<p>A list of power plant specifications. It is provided if type = 'hydropower':</p> <ul style="list-style-type: none"> • efficiency: is a matrix whose first column includes discharge rate (in cms) and the second column turbine efficiency, in [0 1] interval, corresponding to the first column • designHead: A vector of length of two, containing the minimum and maximum design water head (in meter) of the turbine respectively, that the it is in active state • designFlow: A vector of length of two, containing the minimum and maximum design flow rate (in cms) of the turbine respectively, that the it is in active state • turbineAxisElevation: The elevation of axis of the installed turbine (in meter) • submerged: logical: if the turbine is of type of submerged on, TRUE, otherwise, FALSE • loss: losses associated with the turbine (in meter)
penstock	<p>(optional) A list of penstock specifications. It is provided if type = 'hydropower'</p> <ul style="list-style-type: none"> • diameter: The diameter of the penstock (in meter) • length: The length of the penstock (in meter) • roughness: pipe roughness coefficient used for Hazen-Williams formulation
initialStorage	(optional) The initial stored water at the reservoir in the first step of the simulation (MCM). If is missing the the function iterate to carry over the reservoir.
simulation	A list: simulation is a list of three vectors: start, end, and interval. the start and end components must be in 'YYYY-MM-DD' format. the interval component can takes either of 'day', 'week', or 'month'.

Value

the reservoirRouting function returns a list of features given as follows:

- release: a matrix of release(s) equivalent to each demand (MCM)
- spill : a vector of spillage time series (MCM)
- seepage: a vector of seepage time series (MCM)
- storage: a vector of storage time series (MCM)
- loss : a vector of evaporation loss time series (MCM)

```

rippl

Rippl's method

Description

Computes the Rippl-no-failure storage for given set of discharges and target.

Usage

```
rippl(discharge, target, plot=TRUE)
```

Arguments

discharge	a vector of natural discharge at the reservoir site.
target	a vector of demand time series with length equal that of discharge. If the time scale doesn't match, the target will be cycled or truncated.
plot	logical: whether plot the Rippl's method process or merely report the result.

Value

no-failure storage value for the given time series, discharge and target.

risk

risk-based criteria

Description

this function returns risk-based criteria for demand site(s) built-in the object inherited from class of sim.

Usage

```
risk(object , s.const = 0.95)
```

Arguments

object	an object from class of sim
s.const	satisfactory constant: a value in [0, 1] interval, which refers to the level at which if a demand is supplied over the s.const is considered fully supplied.

Details

This function computes the riks criteria based on the formulations proposed by Hashimoto et.al (1982).

Value

a matrix of criteria

Author(s)

Rezgar Arabzadeh

riverRouting	<i>base function for rivers and reaches simulation</i>
--------------	--

Description

Given a sort of demand(s), riverRouting function enable us to simulate rivers and channels under givn a hydrologic time series, inflow, and optional demand(s).

Usage

```
riverRouting(demand=NA, priority = NA, discharge, seepageFraction=NA, simulation)
```

Arguments

demand	(optional) A matrix: is column-wise matrix of demands, at which the rows presents demands for each time step and columns are for different individual demand sites (MCM).
priority	(optional) A vector: is a vector of priorities associated to demand
discharge	(optional) A vector : a vector of water flowing into the diversion (MCM)
seepageFraction	(optional) The seepage coefficient of river discharge flow. The seepage is computed as the product of seepageFraction and river discharge. It is in $[0, 1]$ interval
simulation	A list: simulation is a list of three vectors: start, end, and interval. the start and end components must be in 'YYYY-MM-DD' format. the interval component can takes either of 'day', 'week', or 'month'.

Value

the riverRouting returns a matrix of release(s) corresponding to each demand(s).

set.as	<i>WRSS objects connector</i>
--------	-------------------------------

Description

this function connects a base object as a either of: 'downstream', 'supplier', 'leakageObject', 'seepageObject', or 'divertObject' to a target object, which are both instantiated by WRSS constructors.

Usage

```
set.as(base,target,type='downstream')
```

Arguments

base	An object; from either of classes of createAquifer , createRiver , createReservoir , createJunction , createDiversion , or createDemandSite
target	An object; from either of classes of createAquifer , createRiver , createReservoir , createJunction , createDiversion , or createDemandSite
type	the type of base object to be set as to the target object: 'downstream', 'supplier', 'leakageObject', 'seepageObject', or 'divertObject'

Value

an object from class of target object.
